Since the economical and social impact of congestion can be considerable, the importance of analyzing queueing systems has been clear ever since Erlang's pioneering work on telecommunications at the beginning of the twentieth century. For mathematicians, queues offer an added bonus, namely that the mathematics involved can be complex and intriguing; they also have an enormous potential for varying the conditions and the assumptions of the system. It does not come as a surprise that queues developed quickly into the huge area of study that it is

today. Thousands of papers, and many journals, meetings, and books are entirely devoted to the subject. It is impossible to list here even the key references, and only a small selection will be given, from which other references can be obtained. Among the numerous books, it is worth mentioning the general books of Cox and Smith (1961), Takács (1962), Cooper (1981), Gross and Harris (1985), Medhi (1991), and Nelson (1995); Kleinrock (1975, 1976) and Newell (1982) are good sources of applications; Cooper (1990) is a nice survey with an extensive bibliography. Very useful reviews of many different aspects of queueing theory (including history, statistical analysis, simulation methods, applications, etc.) can be found in Dshalalow (1995, 1997).

Simple queueing systems are defined by specifying the following:

1. *The arrival pattern*, which among other things can be deterministic or stochastic, individual or in batches (like travelers arriving at an airport passport control), etc. Also customers can abandon the line before being served, or can interact in some other ways with the rest of the customers.
2. *The service mechanism*, which describes the number of servers, how many customers at the time the server can handle (usually one, but bulk servers such as buses, elevators, etc. can serve more than one), and the distribution of service times (which can be independent among servers, time-dependent, dependent on queue length, etc.).
3. *Queue discipline*, usually FIFO (first-in-first-out), but others are possible, such as last-in-first-out (LIFO) (as the subroutines in a computer program), priority customers (as express check-out lines, giving priority to shorter service times), customers switching lines, etc. Besides these, other aspects can also be relevant, such as the capacity of the waiting room, or the size of the population of customers.

In the early 1950s, Kendall introduced a useful shorthand notation for simple queueing systems. It consists on a series of symbols separated by slashes, as $A/B/c$. 'A' refers to the distribution of the inter-arrival times between customers; thus Er stands for Erlang, G for General, M for Exponential (Markovian), etc. 'B' characterizes the service distribution for each server, with the same symbols as before, and 'c' refers to the number of servers, who are usually assumed to be equally efficient. More symbols are added when needed, to impose restrictions on the system capacity, and/or on the size of the population that feeds the system, and/or to specify the queue discipline if other than FIFO. One of the simplest and most studied queues is the $M/M/c$ queue, especially the $M/M/1$ and $M/M/\infty$; the latter are particularly useful for modeling self-service facilities or as approximations to systems with a very large number of servers (such as emergency services).

Equilibrium: Measures of Performance

From the probabilistic point of view, properties of queues are usually derived from the properties of stochastic processes associated with them. Let $N(t)$ denote the number of customers in the system at time $t \geq 0$. The *state probabilities* are defined as $P_j(t|\theta) = Pr(N(t) = j|\theta)$, for $j = 0, 1, 2, \ldots$, where θ denotes all parameters governing the arrival and service processes. The derivation of $P_j(t|\theta)$ is crucial in the probabilistic analysis of queueing systems. For many simple systems, the stochastic process $\{N(t),\ t \geq 0\}$ is a birth–death process (a 'birth' occurring with every arrival to the system, and a 'death' with every departure), greatly simplifying their study. (A brief introduction to birth–death, and other, stochastic processes with their connections to queues can be found, for example, in Ross (1993), as well as in the general references for queues given in Section Queueing Systems). More complex systems sometimes resort to studying other *embedded* stochastic (hopefully Markovian) processes by contemplating the system as it would be seen by an arriving customer or by a departing customer.

In all but the simplest queues, determination of these probabilities is, unfortunately, extremely difficult. Often, however, it is possible to determine their large time limit, the so-called *equilibrium* or *steady-state* distribution

$$P_j^{(\theta)} = \lim_{t \to \infty} P_j(t|\theta)$$

without actually having to compute $P_j(t|\theta)$. The equilibrium distribution does not depend on the initial conditions of the system and it is stationary (does not depend on t once the statistical equilibrium is reached). The ergodic conditions give the restrictions on θ under which the system will eventually reach the equilibrium (with probability one). Thus, for instance, in an $M/M/1$ queue, the ergodic condition establishes that the arrival rate (λ) should be smaller than the service rate (μ) (that is, the average number of customers arriving in a unit time is smaller than the average number that the server can handle, a most intuitive condition).

For the most part, queueing theory deals with computations of the steady-state probabilities $P_j(\theta)$, and their use in computing other (steady-state) measures of performance of the queue, such as the expected number of customers in the system and/or in the waiting line, the distribution of the time spent queueing or in the system or their expected values, or the mean (or distribution) of the time the servers are busy (or idle). These steady-state distributions are also often very difficult to compute, and many require solving systems of differential equations, inversion of transforms (generating probability functions, Laplace transforms,…), etc. When only the expected values are required, an extremely useful formula for systems in equilibrium is *Little's law* which establishes that the expected number of customers in the system (L) is equal to the average time that a customer spends in the system (W) times the rate (λ) at which customers enter the system.

Statistical Analysis: A Bayesian Approach

Most of the vast effort in queueing theory has been devoted to the probabilistic development of queueing models and to the study of its mathematical properties; that is, the parameters governing the models are, for the most part, assumed given. Statistical analyses, in which uncertainty is introduced, are comparatively very scarce. A good review is Bhat et al. (1996). It could be argued that the general results of the (well developed) area of inference for stochastic processes (see for instance,

Basawa and Prakasa Rao, 1980; Lehoczky, 1990) could be applied to queues. These general results do not take advantage of the special structure of queueing systems, however, nor do they address its specific questions.

Inference in queueing systems is not easy: From a frequentist perspective, development of the needed sampling distributions can be very involved and often the analysis is restricted to asymptotic results. Also, estimates can be different, for example, if the observational process differ, if the initial queue length is or is not included in the analysis. The statistical analysis is simpler if approached from the Bayesian perspective, and we take this approach below (*see* Bayesian Statistics). More arguments in favor of Bayesian analyses of queueing systems are given in Armero and Bayarri (1999), where a comprehensive list of references with Bayesian analyses of queues is also given. As an illustration of the main issues, the analysis of the much studied *M/M/1* queue is outlined here.

According to the assumptions of the *M/M/1* queue, the interarrival times, Y, are i.i.d. exponential with arrival rate λ, that is

$$f(y/\lambda) = \lambda e^{-\lambda y}, \quad y > 0. \qquad [1]$$

Similarly, the service times X are also i.i.d., $X \sim \mathrm{Ex}(\mu)$, independently of Y, where μ is the service rate. That is

$$f(x/\mu) = \mu e^{-\lambda x}, \quad x > 0. \qquad [2]$$

Steady-state distributions exist if and only if the ergodic condition

$$\rho = \lambda/\mu < 1 \qquad [3]$$

holds, where ρ is the called traffic intensity and plays an important role in the study of $M/M/1$ queues.

A queue can be observed in a variety of ways and different quantities can be recorded. The most traditional experiments (providing complete information) in queues observe the system over a continuous period of time $(0, T]$. T can either be a value fixed in advance, or be determined by a suitable stopping rule. For instance, the system can be observed until the busy time reaches some preassigned fixed value, until a fixed number of customers have departed from the system, until a fixed number of transitions have been recorded, and so on (references can be found in Armero and Bayarri, 1997). Different quantities can be recorded (instants of arrivals, of departures, of commencing of service, number of arrivals and/or departures, interarrival times, service times, number of transitions, busy times, etc). If the queue is assumed to be in equilibrium, the observation of the number of customers at time 0 can also be added, providing more informative but rather cumbersome likelihood functions.

Suppose that an experiment providing n_a interarrival times, $Y_1,\ldots,Y_{na}$ and n_s service completions, $X_1, \ldots, X_{ns}$ has been performed. Then, from [1] and [2], a likelihood function for (λ, μ) based on the observed $\mathbf{x} = (x_1, x_2,\ldots, x_{na})$ and $\mathbf{y} = (y_1, y_2,\ldots, y_{na})$ is

$$\mathrm{L}(\lambda,\mu)\alpha f(\mathrm{x},\mathrm{y}|\lambda,\mu)\alpha\lambda^n a\mu^n s e^{-\mu t_s} \qquad [4]$$

where $t_a = \sum_{i=1}^{n_a} y_i, \quad t_s = \sum_{j=1}^{n_s} x_j$ are the totals of observed interarrival times and service times, respectively. Notice that this likelihood is valid whether n_a and/or n_s are fixed or random (as long as the likelihood function is proportional to [4]). Also, the observation of the arrival and the service processes does not need to be simultaneous and the X's and Y's does not need to correspond to successive customers. (Of course, many of the observational procedures mentioned above result in likelihood functions proportional to [4].) Notice also that [4] applies whether or not the system is in equilibrium and whether or not equilibrium can eventually be reached.

Maximum likelihood estimators are immediate from [4], and given by.

$$\widehat{\lambda} = \frac{n_a}{t_a}, \widehat{\mu} = \frac{n_s}{t_s}, \widehat{p} = \frac{\widehat{\lambda}}{\widehat{\mu}} \qquad [5]$$

However, standard errors of confidence intervals do require careful consideration of the specific stopping rule used, and different experimental designs will in general produce different sampling distributions for these estimators, and hence different standard errors and confidence intervals.

Bayesian analyses are insensitive to (noninformative) stopping rules, and all that it is required from the data is the likelihood function [4]. A prior distribution has also to be assessed quantifying whatever is known about the system before the data is collected. Usually, there is plenty of information a priori about the queue, especially if it is assumed to be in equilibrium (which implies, at the very least, that the system has been working for an extended period of time). A prior distribution incorporating all this information should then be assessed. However, to keep the parallelism with the likelihood analysis and also to avoid the extra work of quantifying subjective beliefs, we use a Bayesian analysis usually called 'objective' because the prior distribution used is of the 'non-informative' or 'objective' type. Since both λ and μ are scale parameters, the invariant measures for each will be used, and they will be assumed independent a priori, that is.

$$\pi(\lambda,\mu)\alpha\frac{1}{\lambda}\ \frac{1}{\mu} \qquad [6]$$

Note that no assumptions about the stationarity of the queue are made in [6]. In fact, they are not needed to produce posterior distributions, although they could be incorporated if desired (see [9] below). If it is wished to incorporate prior information about the values of λ and μ, a very simple prior distribution to use is the conjugate $\pi(\lambda, \mu)\alpha Ga\ (\lambda|a, b)\ Ga\ (\mu|c, d)$, a product of two independent gamma distributions, with the hyperparameters a, b, c, d chosen to reflect the prior information. (Again, this prior makes no assumptions about stationarity). In fact, the prior [6] can be seen as a lmiting case of this conjugate prior when all hyperparameters tend to 0 ('vague' prior information).

Combining [4] with [6] with Bayes theorem, we get the joint posterior distribution

$$\pi(\lambda,\mu/x,y)\alpha\pi(\lambda,\mu)f(\mathrm{x},\mathrm{y}/\lambda,\mu)\alpha Ga(\lambda/n_a,t_a)Ga(\mu/n_s,t_s) \qquad [7]$$

so that λ and μ are independent *a posteriori* with scaled chi-squared distributions $2t_\alpha\lambda \sim \chi^2_{(2n_a)}, \quad 2t_s\mu \sim \chi^2_{(2n_s)}$, and since they are independent, $(t_a/t_s)\rho \sim F_{2na,2n}$, an F distribution. These distributions will be *exactly* valid for all experiments

producing the likelihood function [4], irrespective of the stopping rule. Usual estimates of λ, μ and ρ are the means (or the modes) of their (marginal) posterior distributions, and 'standard errors' associated to these estimates are most naturally given by the standard deviations of those distributions. Intervals with a given probability content can similarly be given. All these will numerically reproduce their non-Bayesian counterparts when the design has n_a and n_s fixed in advance.

An important issue when studying queues is how likely it is that steady-state can be reached. From the marginal distribution of ρ, this and other questions of direct interest can be answered. In particular, the probability that the ergodic condition holds is computed from the F distribution above as

$$\pi_e = \Pr(\rho < 1/\mathrm{x}, \mathrm{y}) = \int_0^1 \pi(\rho|\mathbf{x}, \mathbf{y})\mathrm{dp} = \Psi_{(2n_a, 2n_s)}(t_a/t_s) \quad [8]$$

where $\Psi_{(2n_a,2n_s)}$ is the distribution function of an F_{2na}, $2n_s$ distribution.

Most often, queues are assumed to be in equilibrium. Under this assumption, the restriction $\rho < 1$ imposed by the ergodic conditions should be incorporated into the analysis. This is easily done, and in fact amounts to truncating the unrestricted posterior distribution for ρ giving

$$\pi(\rho|\mathbf{x}, \mathbf{y},\ \rho < 1) = \frac{\pi(\rho|\mathbf{x}, \mathbf{y})}{\pi_e} \quad \text{for } \rho < 1 \quad [9]$$

and $\pi(\rho|\mathbf{x},\ \mathbf{y},\ \rho < 1) = 0$ for $\rho \geq 1$. From [9], estimates, standard errors, credible intervals, etc. that take into account the restriction can be produced. (In this simple case, the probability π_e in [8], the proportionality constant in [9] and the moments of the truncated posterior can be given close form expressions in terms of Gauss' hypergeometric functions.) In Armero and Bayarri (1999), an explicit expression for a factor that can be used for adjusting the usual MLE ρ is given, as well as (adjusted) 'standard errors.' It can there be seen that incorporating the restriction $\rho < 1$ has the effect of 'shrinking' the usual MLE, the shrinkage being larger the larger ρ and the smaller the sample sizes, a most intuitive result.

When statistically analyzing queueing systems, inference about the parameters is rarely (if ever) of direct interest. Usually the main goal is prediction of observable quantities that describe the utilization and degree of congestion of the system. From the Bayesian perspective, it is also very easy to produce predictive distributions incorporating the uncertainty in the estimation of the unknown parameters. The predictive distribution of the steady-state number, N, of customers in the system is computed as

$$\rho(N = n/\mathbf{x}, \mathbf{y},\ \rho < 1) = \int_0^1 \Pr(N = n|\rho)\pi(\rho|\mathbf{x}, \mathbf{y},\ \rho < 1)\mathrm{dp} \quad [10]$$

where $Pr(N = n|\rho)$ is given by the Geometric $Ge(1 - \rho)$ distribution and $\pi(\rho|\mathbf{x},\ \mathbf{y},\ \rho < 1)$ is given in [9]. In this case, again, [10] can be given a close form expression (see Armero and Bayarri, 1994; for details).

Similar arguments apply for prediction of the number of the (steady-state) number of customers in the waiting line, time spent by a customer in the system (or waiting in line), length of busy (idle) periods, etc. All these predictive distributions are a most natural tool for deciding future interventions in the queue (see Armero and Bayarri, 1997).

Conclusion

Queues systems are useful to stochastically model systems in which subjects interact and congestion occurs. They can describe a wide variety of such situations, in virtually all areas of application. In probabilistic terms, queues have been extensively studied under the assumption that the governing parameters are known. Inferences about these parameters can be very challenging when approached from a frequentist perspective, and the common approach of simply replacing the unknown parameters by some estimates when predicting measures of performance of the queues can produce deceiving results. Bayesian methods appear to be ideally suited to handle inferential aims in queuing systems, as incorporating restrictions in the parameter space (imposed by the ergodic conditions), predicting measures of performance, designing the system, etc. Moreover, its independence of the stopping rule makes the inferential task much simpler.

Abstract

This article reviews contemporary research on achievement motivation in racial/ethnic minority youth. The review is organized around two main constructs in motivation research: expectancy for success, or beliefs about ability (Can I do it?) and how much that success is valued or desired (Do I want it?). The topics covered under expectancy for success are racial stereotypes about intelligence, students' implicit theories about intelligence, and coping with discrimination. The topics covered under achievement values are oppositional identity, the valued characteristics of peers, self-affirmation, and the immigrant paradox. Implications for interventions to improve motivation in ethnic minority youth are discussed.

Motivation is the study of *why* people behave as they do: what energizes them to start behaving in a particular way, what directs their behavior and keeps them going, and what leads them to eventually terminate the behavior. In the achievement domain, think about a typical behavior such as a student studying for an exam, and view it as a temporal sequence that is initiated, directed, sustained, and then terminated. Motivation researchers examine what the student is doing, or behavioral *choice*; how long it takes before the student begins to study, or the *latency* of behavior; how hard the student actually studies, or behavioral *intensity*; how long the student is willing to study, or the *persistence* of behavior; and what the student is thinking and feeling during or after the study session, or the *cognitions and emotions* that accompany or follow the behavior.

There are a few dominant contemporary approaches to motivation that address one or more of these temporally ordered constructs (see review in Graham and Weiner, 2011). The most popular of these approaches fit broadly within an expectancy-value framework. Motivation (e.g., choice, latency, persistence) is determined by both the likelihood of goal attainment, which is the expectancy component, and how much that goal is desired, which is the value component. The study of expectancy addresses beliefs about ability (Can I do it?), whereas the study of values addresses preferences and desires (Do I want it?). The notions of *can* and *want* closely correspond to the distinctions between aptitude and effort expenditure, which are two of the most important determinants of the motivation to achieve.

This article on race and motivation is organized around overarching questions about *can* and *want*. In so doing, it departs from the general motivation literature in two ways. First, the starting point is the larger sociocultural context and factors that are unique to the everyday lives of people of color. Some of those factors are historical and structural in nature. Many racial and ethnic minority groups are positioned at the bottom of a status hierarchy wherein barriers to opportunity often override personal strivings for achievement. Second, race and motivation are examined from a social contextual perspective. Central to that perspective is the belief that students' social lives and their academic lives are interrelated and that one cannot fully understand an individual student's motivation to achieve without also understanding their relationships with other people. The social nature of motivation is particularly important during adolescence when peer approval takes on heightened significance.

With this framework in mind, the first part of the article addresses beliefs about ability (Can I do it?) and how these beliefs are shaped by racial stereotypes about intelligence, students' implicit theories about intelligence, and coping with discrimination. The second part of the article turns to achievement values (Do I want it?) in which the focus is on oppositional identity, the valued characteristics of peers, self-affirmation, and the immigrant paradox. Addressing these topics highlights the unique motivational challenges of racial and ethnic minority youth as they strive to master their environment.

Beliefs about Ability: Can I Do It?

Racial Stereotypes about Ability

Stereotypes are culturally shared beliefs, both positive and negative, about the characteristics and behaviors of particular groups. Even though beliefs about African-Americans have become more positive over the last 50 years, studies of cultural stereotypes continue to show that respondents associate being black (and male) with hostility, aggressiveness, violence, and danger (e.g., Correll et al., 2002). The recent acquittal in Florida of George Zimmerman for the murder of Trayvon Martin, an unarmed black youth, is a stark reminder of that fact. The much smaller stereotype literature on other ethnic groups in the United States also portrays the more marginalized groups in a negative light. For example, cultural stereotypes of Latino

youth depict them as unintelligent and with little personal ambition (e.g., Kao, 2000).

African-Americans and Stereotype Threat

Research on stereotype threat (Steele, 2010) has provided important insights into the negative consequences of racial stereotypes about intelligence. Stereotype threat is the awareness that individuals have about negative stereotypes associated with their group. Although considered to be a general psychological state applicable to any negative group stereotype, the construct originated in the achievement domain and it has been applied to African-American students' awareness of the cultural stereotype associating their race with intellectual inferiority. That awareness can be quite debilitating, especially for those African-American students who are invested in doing well in school. For example, in a series of studies with black and white students attending Stanford University, Steele and colleagues found that black students performed more poorly than whites on standardized test items when they were told that the test was diagnostic of their abilities. When told that the test was a problem-solving activity unrelated to ability, there was no difference in the performance of the two racial groups. In ability-related contexts, therefore, what became threatening for black students was the fear that they might confirm the stereotype or be judged by others based on that stereotype. Stereotype-threatened students often are dividing their attention between the task itself (e.g., taking a SAT exam) and ruminating about the meaning of their performance (e.g., what does this say about me or about members of my racial group?). Such negative ruminations have been shown to both arouse anxiety and deplete the executive resources needed to do well on academic tasks. Furthermore, it is not necessary that a student endorse the stereotype; mere awareness of its existence is sufficient to activate threat.

Stereotype threat researchers have documented two motivational consequences of the anxiety associated with thinking about race and intelligence in highly evaluative achievement contexts. Some students may choose to work especially hard as a way of disconfirming the stereotype; but high effort in the face of increasing academic challenge may be difficult to sustain and may even lead one to question their abilities. Stereotype threat can also have the opposite effect, causing students to minimize effort and downplay the importance of doing well in school. Steele coined the term academic *disidentification* to describe students who no longer view academic achievement as a domain that is either important to them or their self-definition. Disidentification has been associated with declining achievement from middle-school to high-school, particularly among African-American boys. A similar process, labeled academic *disengagement*, occurs when students begin to discount the feedback they receive about their performance or to devalue achievement altogether. While disidentification and disengagement may be self-protecting mechanisms for coping with negative racial stereotypes, in the long run their detrimental effects on motivation will outweigh any short-term self-enhancing effects.

In the last two decades, hundreds of studies on stereotype threat have been conducted and the Steele and Aronson (1995) inaugural article is considered to be a modern classic in social psychology (Devine and Brodish, 2003). However, it is also important to point out that the phenomenon is not without its critics (e.g., Sackett et al., 2004). Most of the studies are laboratory-experimental in which threat is activated by some experimental manipulation, leading to questions about ecological validity. It is also not clear that undoing stereotype threat actually reduces the racial achievement gap, which some supporters of the theory have proposed. Moreover, few studies thus far have been conducted with children in elementary and secondary schools, which raise issues about the age at which stereotype threat begins to affect motivation and performance of racial minority groups. The absence of a developmental literature is probably one of the major limitations of this literature.

Asian-Americans and the Model Minority Stereotype

There is also a literature on the motivational effects of racial stereotypes about intelligence at the other end of the ability spectrum. Unlike African-Americans, the cultural stereotype about Asian-Americans is that they are hardworking and intellectually gifted high achievers who are especially competent in math and science. The term *model minority* was coined in the 1960s to capture those characteristics and to account for the seemingly unprecedented successful entry of East-Asian immigrants into mainstream American society. Many studies have now documented that Asians and non-Asians alike are aware of the culturally shared association between high academic achievement strivings and being an Asian-American (e.g., Kao, 2000).

While it may be more tolerable to know that one's racial group is viewed as smart and hardworking rather than dumb and lazy, that stereotype also has its own set of challenges. Ethnographic, survey, and experimental research all point to psychological and emotional costs associated with living up to the model minority stereotype. Ethnographic studies, for example, detail the anxiety that many Asian-American students feel when forced to cope with the perception of their group as academic superstars. Many report feeling frustrated and pressured to attain or maintain high academic achievement because of the expectations placed upon them by their parents and teachers. Thus, while some African-American students worry that their performance might confirm a negative stereotype, some Asian-American students worry that their performance might not confirm a positive stereotype. These worries may be exacerbated among groups from Southeast Asia (e.g., Cambodians, Laos) whose immigrant experiences have been quite different from those of their East Asian and South Asian counterparts (Ngo and Lee, 2007). Southeast Asian students may be derogated by teachers and authority figures because of their lower-academic achievement yet not enjoy any of the social benefits of being perceived as a model minority.

Entity versus Incremental Theories about Intelligence

Whether individuals are vulnerable to racial stereotypes or other challenges to 'I can' is in part determined by their beliefs about the meaning of intelligence. For example, does it make a difference if students view their abilities as stable and

essentially beyond their control ("either you have it or you don't") or as changeable and largely determined by how much effort they exert? To address this question, Dweck proposed a distinction between individuals who hold entity versus incremental theories of intelligence (Dweck, 2006). Some individuals are entity theorists: they believe that intelligence is basically fixed, each person has their allotted share, and there is little they can do to increase that allotment. In contrast, other individuals appear to be incremental theorists: they believe that intelligence is modifiable through increased effort. These implicit theories have been related to a variety of achievement-related cognitions and behaviors. For example, students who subscribe to an incremental theory of intelligence prefer challenging tasks so that they can both increase their ability and achieve greater mastery. Entity theorists, on the other hand, often avoid challenge because their primary concern is with the adequacy of their presumably fixed ability and what failure might convey about that ability.

It should be evident that the negative motivational consequences of an entity theory of intelligence resemble the vulnerability to stereotype threat discussed above. Recognizing this overlap, a number of social psychologists have designed interventions for stereotype-threatened students that focus on changing beliefs about intelligence (see review in Yeager and Walton, 2011). In these interventions, ethnic minority college students and middle-school students were trained to view intelligence as malleable rather than fixed. For example, in one representative study with middle-school students, African-American and Latino seventh graders who were struggling in math were randomly assigned to an incremental theory experimental condition or to a control condition (Blackwell et al., 2007). The intervention group received eight weekly lessons on how the brain works, emphasizing its plasticity and malleability (e.g., one lesson was entitled "You Can Grow Your Intelligence"). Compared to control-group classmates, those in the treatment group showed significant improvement in math performance over a 1-year period. The greatest improvements were found for those who changed their theories of intelligence from entity to incremental beliefs, suggesting that the intervention was effective in changing a very specific kind of maladaptive motivational belief.

Coping with Discrimination

Like people who hold entity theories of intelligence, individuals of color who believe that they are treated unfairly because of their race or ethnicity can lose confidence in themselves and their willingness to persist in the face of academic challenge. Among the most prevalent kinds of unfair treatment reported by ethnic minority youth are receiving a lower grade than deserved from teachers, being the recipient of unusually harsh discipline from authority figures, being accused of behaving suspiciously in public places, and being the target of verbal, psychological, or physical abuse from peers at school (Fisher et al., 2000).

Racial discrimination can take its toll on the mental, physical, and academic well-being of youth. Such experiences have been linked to decreased perceptions of mastery among early adolescents of color and increased negative attitudes about school. Perceived discrimination can lead to mistrust of teachers and to the general belief that the school rules and policies are unfair. In an effort to offer a more nuanced approach to the experience of discrimination, recent research has also documented that different sources of unfair treatment might be related to different outcomes (Benner and Graham, 2013). For example, does it make a difference if the perpetrators are peers versus teachers? It appears that race-based unfair treatment by peers (e.g., physical bullying, ostracism) is uniquely linked to mental health difficulties, whereas perceived discrimination by teachers (e.g., discipline or assignment of grades) is more directly predictive of academic disengagement. Because Asian students are more likely to report maltreatment from peers and African-American students are more likely to perceive teacher discrimination (Rosenbloom and Way, 2004), it is important to identify the particular negative consequences of each discrimination source.

Not all ethnic minority youth succumb to the motivational challenges of perceived discrimination. There may be some circumstances under which youth transform discriminatory experiences so that they become an impetus for increased effort in school. Eccles et al. (2006) asked middle-school youth whether they believed that being African-American would make it difficult for them to be successful in their future educational and occupational pursuits. Analyses showed that youth who anticipated future race-based discrimination displayed *higher* levels of academic motivation than those who did not. Rather than focusing on day-to-day discrimination experiences, some youth may conceptualize unfair treatment as a structural barrier that can be overcome through academic excellence.

Perhaps the best antidote to the negative effects of perceived discrimination is a combination of strong racial/ethnic identity and parental socialization about race. For example, when African-American youth report that their race is central to their self-concept and that parental messages communicated both racial pride and vigilance (preparation) against racism, then the relations between experiences with discrimination and academic disengagement were weakened (e.g., Neblett et al., 2008). It appears that a moderate amount of preparation for bias and discrimination is most effective. Too little parental socialization may leave ethnic minority children adolescents vulnerable to the harmful impact of discrimination whereas too much preparation could heighten awareness of racial barriers to a level that results in the erosion of children's self-efficacy (Harris-Britt et al., 2007).

To summarize, this section of the article focused on how beliefs about ability can be challenged for ethnic minority youth. Such youth must cope with stereotypes linking race to low or high intelligence and with the widely shared perception that intelligence is a fixed entity that cannot be changed. These youth also confront discrimination, both overt and subtle, that can undermine achievement strivings. Seeing race or ethnicity as central to one's identity and receiving a moderate level of parental messages that prepare one for racism can buffer some of the negative consequences of discrimination.

Beliefs about Effort: I Can, but Do I *Want* to?

This next section focuses on the second main construct in contemporary motivation research – achievement values. Unlike expectancy, which is largely about ability beliefs, values

have to do with desires and preferences and are more concerned with the perceived importance, attractiveness, or usefulness of achievement activities. Like expectancies, values have motivational significance because they guide thoughts, feelings, and behavior. For example, what we judge to be important, attractive, or useful can influence the activities we choose, how we evaluate other people and events, and our worldviews. Values also are rooted in the moral constructs of 'ought' and 'should' as illustrated by the belief that one should try hard in school regardless of their perceived abilities. Particularly during adolescence, trying hard in school is sometimes compromised because of the tension between the need to achieve and the need to belong, both of which are fundamental human motives. The sociologist James Coleman astutely observed more than 50 years ago that adolescents care more about being popular than being perceived as smart and that they even downplay effort in order to be liked by popular peers (Coleman, 1961).

Oppositional Identity

The tension between having friends and being a high achiever can play out in particular ways for youth of color, African-American youth in particular, in a phenomenon emerging from anthropological analyses known as oppositional identity (Fordham and Ogbu, 1986). African-Americans and some Latino groups have been labeled as an involuntary minority – that is, a group which has become part of the American fabric not by choice, but as a result of slavery, conquest, or colonization. One consequence of this history is that acceptance of mainstream values about working hard and school success may be perceived as threatening to one's social identity. Particularly during adolescence, African-American and Latino youth may adopt oppositional identities whereby they show relative indifference, or even disdain toward achievement behaviors that are valued by the larger society. Fordham and Ogbu (1986) coined the term *acting white* to describe African-American high-school students' perceptions of their same race peers who work hard to do well in school. Antiachievement peer group pressure from involuntary minorities can take many forms, including being labeled an 'oreo' or 'sellout,' social ostracism, and even physical assault (Kao, 2000).

The discourse surrounding oppositional identity during adolescence has remained active, in part because it provides a motivational explanation for the achievement gap between black and white students (Downey, 2008). One would be hard-pressed to find an article on academic motivation in African-American adolescents in the last 20 years that does not explicitly or implicitly make reference to oppositional identity. That construct also has been linked to other motivational phenomena discussed earlier in this article, such as stereotype threat and disidentification, as a way to fully capture the motivational challenges that African-American students face.

Other than the rich qualitative studies that followed Fordham and Ogbu's inaugural research, there is not a lot of hard evidence that black students or members of other involuntary minority groups endorse the attitudes assumed by an oppositional identity perspective. For example, survey methods were used to test hypotheses about oppositional identity with data from the National Education Longitudinal Study, a nationally representative panel study of 25 000 ethnically diverse students who were assessed in 8th, 10th, and 12th grade (see review in Downey, 2008). Contrary to predictions from oppositional identity, black students in these analyses were more likely than white students to endorse positive school attitudes and just as likely to hold high educational aspirations (although they were doing more poorly in school). What is true – and what may be the lasting contribution of the oppositional identity literature – is that some high-achieving students of color experience a particular kind of conflict between achievement strivings and their desire to be accepted by members of their racial/ethnic group and this conflict may at times interfere with their motivation to do well in school.

Characteristics of Valued Peers

Survey methods that directly ask students of color whether they value effort in school sometimes yield inconclusive findings, in part because of the social desirability built into such questions (almost everyone agrees that effort is important). Recent motivation research has offered less reactive ways to measure the degree to which students of color report that they value working hard and doing well in school. For example, Taylor and Graham (2007) used peer nomination procedures in which they asked elementary and middle-school African-American and Latino youth to list the names of classmates whom they admire, respect, and want to be like. The rationale for these questions was that if researchers can identify the characteristics of classmates whom a student admires, respects, and wants to be like, this tells us something about the characteristics that the student values. A conceptually similar approach (the 'admiration ladder') was used in early motivation training work to enhance the achievement motive. Taylor and Graham (2007) were particularly interested in how nominations as someone that the nominator admired, respected, and wanted to be liked varied as a function of the achievement level of the person nominated. The research documented that girls of all grade levels overwhelmingly nominated high achievers as classmates they most valued, whereas boys were less likely to nominate high-achieving peers as they approached middle-school. By the time African-American and Latino boys reached adolescence, they appeared to look more admiringly upon less academically inclined peers.

Such findings highlight the particular motivational challenges of ethnic minority males, a gender pattern that has not adequately been acknowledged. In mainstream gender research on motivation, a dominant theme is the heightened vulnerability of girls to motivational deficits (Meece and Askew, 2011). The argument is that gender role socialization and cultural stereotypes about women and achievement lead many girls to question their academic competence more than boys, particularly in math; to display more maladaptive reactions to failure, and to perceive more barriers to success. However, these arguments may need to be reframed because it is evident that ethnic minority males (i.e., African-American and Latino) are faring more poorly than females (e.g., Way and Chu, 2004). The ethnicity by gender differences increase across the school years and are particularly apparent when the measures are so-called markers of adolescent success (i.e., high-school graduation) and young adult mobility (i.e., enrollment in and

completion of college). Harsh disciplinary practices like school suspension also fall disproportionately on African-American males (American Psychological Association, 2008). These findings indicate that ethnic minority boys, more than girls, must cope in unique ways with the dual stressors of academic challenge and stereotypes about their group and these stressors can undermine the endorsement of achievement values.

Self-Affirmation

Self-affirmation theorists have examined how an opportunity to express one's core personal values can have positive motivational consequences. In one novel intervention, Cohen et al. (2009) had African-American and white middle-school students choose from a set of values (including those related to achievement) the two or three that were most important to them and to write a paragraph about why they selected those values. Students in the control condition wrote about the values that were least important to them. The rationale for the intervention was that reflecting on personally important values can be self-affirming and can therefore buffer some of the challenges associated with ethnic minority status. This simple intervention yielded powerful effects. African-American students in the values affirmation condition attained higher grades over the course of the school year and were actually able to reduce the achievement gap between black and white students.

Achievement Values and the Immigrant Paradox

Driven largely by immigration during the past 40 years, the racial and ethnic landscape in the United States has been dramatically redrawn. Although whites are still the majority group in the nation as a whole, Asians and Latinos are now the fastest growing ethnic groups. In some states, like California and Texas for example, that growth has been so dramatic that it is no longer meaningful to talk about majority and minority groups inasmuch as no single ethnic group holds the numerical balance of power. The increased presence of immigrant children of color in the schools has led to an interest in the impact of acculturation on academic motivation (see Urdan, 2011). As schools become more multicultural, immigrant students cope simultaneously with increased cross-ethnic contact and pressures to adjust to the dominant culture. These acculturation pressures have largely been studied in the context of children's valuing of effort and doing well in school.

One of the most provocative findings in the literature on motivation among immigrant groups is the so-called immigrant paradox. Defying 'melting pot' theories that outcomes improve across longer residence in the host culture, recent research has documented that many immigrant groups do more poorly across successive generations of residence in the United States (Garcia-Coll and Marks, 2011). For example, in some studies first- and second-generation adolescents of Latino, Asian, or black (Caribbean) descent did better in school and maintained more positive attitudes about achievement than did same-ethnicity youth whose families had resided in this country for three or more generations. This phenomenon has been labeled a paradox because immigrant youth tend to have less well-educated parents and be of lower socioeconomic status than native-born peers.

Communicated parental values about hard work, the importance of a good education, and family obligation appear to be among the most important factors accounting for higher achievement strivings among immigrants and children of immigrants (second generation) compared to their counterparts of third generation and beyond. Family obligation refers to how much family members feel a sense of duty to help one another and to take into account family needs when making personal decisions (Fuligni, 2001). It has been shown that Latino and Asian immigrant youth are more likely than their American-born counterparts to report a belief in family duty. Family obligation, in turn, is correlated with achievement values inasmuch as many of the youth feel that doing well in school is something that they owe their parents.

Conclusions

This discussion of motivation in racial/ethnic minority youth has focused on the challenges to expectancy and value, in part due to structural barriers that often accompany minority status in the United States. But it is also important to acknowledge resilience in youth of color and successful intervention efforts to overcome those challenges. There are promising motivation interventions, such as those related to beliefs about intelligence and self-affirmation, that foster achievement strivings among youth at risk for school failure. These interventions have generated a good deal of excitement because of their potential to deliver short but powerful treatments that not only boost immediate achievement but also reduce the racial achievement gap (see review in Yeager and Walton, 2011). However, given the structural barriers that influence both *can* and *want*, it may be unrealistic to think that changing one set of beliefs – be it worries about confirming racial stereotypes, implicit theories about intelligence, or the importance of affirming personal values – will have lasting effects on motivation and achievement no matter how powerfully they are delivered. Multifaceted approaches that address multiple belief systems are probably needed.

Furthermore, the burden for motivational change to enhance achievement should not remain solely with the individual student. In light of challenges to perceptions of 'I can,' teachers need to be especially vigilant about not employing instructional practices that can indirectly and unintentionally communicate low-ability messages or activate stereotype threat. For example, it has been documented that undifferentiated praise for success at easy tasks, unsolicited offers of help, and too much sympathy following failure can lead students to attribute their academic setbacks to low ability (Graham, 1991; Rattan et al., 2012). Furthermore, altering pedagogical practices to be more effort- rather than ability-oriented can have immediate impact on students' motivation, even among those who are highly identified with the achievement domain. Cohen et al. (1999) found that African-American college students displayed more subsequent task motivation when feedback about poor performance was accompanied by criticism and communicated high expectations than when the same criticism

was accompanied by general praise as a buffer. Such wise feedback can shift the attribution for failure away from low ability and toward those factors such as lack of effort that are under volitional control. And school administrators should become more sensitized to how policies related to discipline, such as suspension and expulsion, can promote perception of barriers to opportunity and discrimination among ethnic minority adolescents (APA Task Force, 2008). In other words, there are both individual-level variables and structural or systemic factors that need to be targets of motivational interventions for ethnic minority students. Such a multilevel approach, albeit challenging, will be the best way for motivation researchers to bring their expertise to bear on ways to enhance the achievement striving of ethnic minority youth and make it last.

Race and Racism in the Twenty-First Century

Yolanda T Moses, University of California Riverside, Riverside, CA, USA

Abstract

Race and racism in the contemporary globalized world is a product of historical forces that still resonate today. With a focus on the United States and its relation to race–racism research both in the United States and abroad. By reexamining the Atlantic slave trade, social scientists and historians tie its establishment to the development of the modern world economy. This article then examines the specific ways that these linkages are still operative in the United States and globally. The author also suggests new research strategies for understanding the specific ways to expose the depth of these structural racial inequalities, and how to begin to eradicate them.

Racial Formation in the Twentieth Century by Omi and Winant (1984, 1994, 2002) provided a framework through which sociologists, anthropologists, and others could locate the role of race in structuring broader social formations. It was quite useful to use to look at the political and social terrain of the 1970s and 1990s in the United States, especially. It arose at the same time politically that the conservatives and neoliberals were forging a 'new world order' that introduced the concepts of 'colorblindness' and 'postracial America' that one still hears echoed among conservatives during the first Obama administration (Goodman et al., 2012). Also, in the 1990s, anthropologists, sociologists, and biologists reaffirmed the fact that race as a biological construct was not real, but was an illusion, a social construct (Mukhopadhyay and Moses, 1997; Goodman et al., 2012; Smedley, 1993). Omi and Winant challenged that benign view by indicating that race was not an illusion, but was very much a foundational axis of American society (Omi and Winant, 2012: p. 14). Mullings, Harrison, and others also comment that anthropologists, by denying the biological basis of race, actually left a void and a vacuum to talk about what race really was, and how it continued to operate as a powerful social construction (Mullings, 2005; Harrison, 1995). It was Mukhopadhyay and Moses in 1997 who challenged the field of American anthropology to reestablish race in its anthropological discourse (Mukhopadhyay and Moses, 1997). Since then, anthropologists have looked at the social construction of race and racism from many perspectives, including intersectionality of issues like gender, sexual orientation, class, and identity (Mullings, 1997; Bolles, 2001; McClaurin, 2001); power and hegemony (Sanjek, 1998; Smith, 2012); globalization and capitalism (Wade, 2003; Brodkin, 2000); genetics and genomics (Goodman et al., 2012; Bliss, 2012); immigration, migration, and transnationalism (Kearney, 1995); racial critique of the discipline of anthropology itself (Baker, 1998; Mullings, 2005; Marks, 2005; Blakey, 1997; Harrison, 2008; Susser and Patterson, 2001); antiracism research (Mullings, 2005); and the future of race–racism in the United States and the world (Winant, 2001; Goodman et al., 2012).

Pushing the Racial Formation Paradigm

Since the 1990s, there have been developments in the research on race in the United States and abroad that both critique and build on the foundation of Omi and Winant's work. The edited book *Racial Formation in the 21st Century* (2012) is a place to begin this critique and new vision of racial formation and its processes. In the introduction, while paying homage to Omi and Winant, the editors, HoSang, LaBennett, and Pulido point out at least three ways that *Racial Formation in the 20th Century* fell short. They are specifically that Omi and Winant focus too much on the United States as the global model for race, there was a conflation of the concept of race and ethnicity, and class is treated in a dismissive way (2012: p. 6). This book goes on to take a holistic view of new racial theory formation since the original Omi and Winant publication, as well as what they call dialogues and conversations with other racial formation theories that were also in circulation during the 1990s. Two of these theories are critical race theory (Crenshaw, 1991; Crenshaw et al., 1995) and intersectionality theory (Crenshaw et al., 1995; Twine, 1998). Racial formation theory of Omi and Winant did tackle the issue of ethnicity in the United States by explaining that ethnicity is a process by which individuals and groups (come) to understand, or understand themselves as separate or different from others based on social practices such as language, religion, rituals, and other patterns of behavior. In this analysis, they note that the use of the term ethnicity instead of race offers the opportunity for conservatives and neoliberal policies to question or negate the legal and policy gains of people of color in this country, when new policies and programs are focused not on race, but on the creation of a 'colorblind society,' which ignore the history and the intractability of structural racism (Goodman et al., 2012).

Other racial theorists outside the fields of sociology and anthropology, such as Thomas Holt (2002) in history and Paul Gilroy (1993, 2002) in cultural studies and American studies have used the concept of Omi and Winant's racial formation to build theoretical frameworks to better understand and explain the history of the formation of black expressive culture, black diasporic identity, and hybridity. Winant (2000, 2001) argues that there was no such thing as race in classical antiquity. Isaac in his book *The Invention of Racism in Classical Antiquity* did find what he calls significant examples of 'protoracism' in Greek and Roman literature, "despite his observance that racism did not exist in its current form of biological determinism, nor was there any systematic persecution of any ethnic group or another." Other historians and anthropologists also found it useful to make a distinction

between prototypical forms and the systematic racial classification that took center stage over the past two centuries in our modern world (Smedley, 1993). Indeed, Mullings contends that a reexamination of history and race, especially the slave trade puts the concept of race in a different light (2005). Historians like Holt (2002), and anthropologists like Brodkin (2000) along with Winant (2001) all tie the centrality of the African enslaved labor trade to the development of the modern capitalist world economy. Stuart Hall and Paul duGay (1996) and his concept of new ethnicities fall in line with how literary studies have conceptualized race and ethnicity. This field has highlighted how over recent years transnational literacy influences multilingual traditions that traverse national boundaries, and that new multinational public spheres are produced by the translation of diverse texts, ideas, and people. HoSang, Bennett, and Pulido also note that by focusing on the circuits of ethnicity formation in conjunction with racial formation and exploring these relations in and across nations, such studies began to diverge from sociological models of racial formation in which the state plays a central role (HoSang et al., 2012: p. 9). In other words, the sheer movement of vastly diverse groups of people is producing especially for the late twentieth and early twenty-first centuries, new ways of thinking about and enacting racial formation on a global scale. Paul Gilroy in *Black Atlantic* (1993) emphasizes the common global routes that historically link black expressive culture. Foregrounding common experiences of oppression rather than defining blackness in relation to Africa as an 'actual or mythical' homeland, Gilroy was able to conceptualize black communities as constructed in defiance of racial essentialism and as connected through popular cultural productions (Gilroy, 1993).

Racial Formation in the Twenty-First Century

Racial Formation in the Twenty-First Century takes us to old and new intersections, beyond the borders of the United States, back to biology and back to the unfinished job of dismantling structural racism here in the United States and beyond. Research in the area of intersectionality in the twenty-first century examines how sociopolitical categories and identities based in race, gender, and class interact, sometimes systematically structuring social inequality and injustice, and sometimes profoundly challenging such social structures. This notion of challenging structures builds on Kimberle Crenshaw's concept of intersectionality (1991) that sought to explain how the experiences of women of color are "simultaneously the product of intersecting patterns of racism and sexism, and how these experiences tend not to be represented within the discourses of either feminism (read white women) or anti-racism (read men of color)" (Crenshaw, 1991: p. 299). Priya Kandaswamy (2012) points in this new direction as she builds on legal scholar Crenshaw's model and suggests that racial formation is fundamentally a gendered and sexualized process and further argues that viewing race as unstable, historically produced, and changing in the ways that Omi and Winant demonstrates complicates the meaning of intersectionality (Kandaswamy, 2012: p. 24). For her, it is precisely the intentional interrogation of the historical embeddedness of race, gender, sexuality, and class with each other that will produce new theories of intersectionality. In a similar vein, Ferguson (2012) challenges the historiographical framework proposed by Omi and Winant in *Racial Formation* that helped to theorize US national liberation movements as more than instances and outcomes of social agitation, showing that they were historiographical provocations that pushed people in the United States to think differently about racial difference and identity. He is fine with the theorizing, but he feels that they leave out a significant group of people who were not officially a part of the national civil rights or national liberation movements of the time. He says "those [smaller] movements were initiated by women of color and queers of color within the United States. Indeed, reperiodizing anti-racist politics according to the emergence of those movements constituted by people of color who were marginalized by sexuality and gender allows us not only to observe the specificities of civil rights and national liberation movements but also to see how race and anti-racist politics were rearticulated in those very movements…" (Ferguson, 2012: p. 45).

Andrea Smith (2012) moves us in still another direction that links indigeneity, settler colonialism, and the uninterrogated terrain of white supremacy. In her article, she challenges the very racial theory framework that is used in Ethnic Studies and Native Studies programs. She agrees that "native peoples are treated as ethnic groups suffering from discrimination rather than as nations undergoing colonization, and that these two groups should get together to discuss that erroneous framework … at the same time because of this political and intellectual divide, there is little dialogue among them that would help us to understand how white supremacy and settler colonialism intersect, especially in the United States" (2012: p. 66). In this chapter, she argues that scholars' lack of attention to settler colonialism hinders the analysis of race and white supremacy developed by scholars who focus on race. In the end, she focuses on ways that native scholars and practitioners can rearticulate their relationship with the land, and with the white power structure (2012: p. 88).

Where does one go from here? Future research should focus among other things on relationships among antiracist, women's, anticolonial/anti-imperial, and labor-based/antipoverty movements. There is also a powerful 'intersectionality' that exists on the political right (especially in the United States), where antifeminist, antilabor, 'blame the victim'-oriented, homophobic, and ambiguously antiracist orientations operate and need to be interrogated. There is a need for more research that investigates the instability in practice of intersectional situations and social structures. For example, how do individuals and movements navigate among the raced, gendered, queer, class, and caste-based dimensions of social, cultural, and political life; what is the relationship between intersectionality and indignity; what are the elusive linkages among axes of identity and difference, and those between alliance and antagonism? There is also a continuous need for historical views of intersectionality both in the United States and transnationally. Even more fundamentally, what are the emerging contested views and definitions of intersectionality itself? Is intersectionality in both local and global contexts different? If so, how? How are intersectionality

and postcolonialism connected, and what are the newly emerging theories around intersectionality and the politics of identity? Finally, theoretical frameworks and methodologies are needed that highlight micro–macro linkage problems and social movements in particular comparative and historical contexts.

Race and Racism beyond the Borders of the United States

For the past two decades, scholars in anthropology, sociology, and other fields have looked at issues of immigration, transnationalism, race and ethnicity, diasporic studies (Ong, 1999), and intersectionality through cross-cultural, transnational, and global lenses. The idea of race and the hierarchical institutionalization of racial difference emerged dialectically in relation to sixteenth-century economic transformations that ultimately created what is now known as 'the modern West' (Holt, 2002). While notions of difference operated prior to this period, the expulsion of Muslims from Europe, the initial European voyages of exploration and discovery, and the development of mercantile trade generated a novel situation whereby, for the first time, racialized labor became crucial to the mobilization of productive forces on a world scale (Holt, 2002: p. 32; Thomas and Clark, 2006). At the same time that the associations between nation building and imperialism and between racial slavery and the development of export-oriented mass agricultural production became more tightly integrated, new philosophical and scientific ideologies began to circulate in Europe about the nature of man. Within religious, philosophical, scientific, and political discourses, hierarchies of human value over time were mapped onto gendered, racial, and civilizational differences (Thomas and Clark, 2006; Goodman et al., 2012).

In this way, early state formation (in the old and new worlds) and mercantile capitalism inaugurated material and ideological processes that indelibly linked the 'New World' and the 'Old' in a common project of defining people in a commodified social hierarchy that was expressed in gendered racial and class terms. In other words, the development of a highly structured social and economic system in the New World is the direct result of Imperial conquest (by Europeans), plantation slavery, and structural racial domination. These new racialized processes also had an impact back home on metropolitan Europe as well. According to Gilroy (2002) and Thomas and Clark (2006), this formulation of the modern world conceptualizes the Atlantic Ocean as an integrated geohistorical unit in which the structural transformations associated with early European expansion westward created what ultimately became a triangular web of political, economic, and sociocultural relations joining individuals, communities, and classes on three continents in a single sphere of interaction (Thomas and Clark, 2006; Mullings, 2005; Mukhopadhyay et al., 2007).

Three Hundred Years and Counting

Imperialism, slavery, and colonial exploitation in the fifteenth, sixteenth, and seventeenth centuries created enduring global linkages that were sustained through the postemancipation period of the mid-nineteenth century and into the twentieth and twenty-first centuries. At the same time when the age of exploration was taking place in the fifteenth and sixteenth centuries, both science and religion colluded (sometimes consciously and sometimes not) as the two dominant discourses of colonialization and the institutionalization of a permanent racial hierarchy in the Americas, Africa, and South Asia. Advocates for slavery and colonial expansion helped to institutionalize the new science of anthropology, in part to counter Abolitionists' claims based on morality and biblical tenets. As the discipline developed during the late nineteenth century, human difference was parsed along a color-coded hierarchy from savage to civilized – from black through brown, yellow, and red to white (Baker, 1998; Thomas and Clark, 2006; Goodman et al., 2012). The fact that some researchers documented customs and behaviors while others measured brains and bodies did not change this hierarchy because human diversity and cultural differences were blurred and racially mapped in a way that privileged biology as the basis for human difference, with those in power being male Europeans.

However, other changes were afoot in the early twentieth century as altered relationships between the means of production and local and global consumption that also had a hand in transforming racial meanings once again. The rise of resistance movements such as Garveyism and Pan-Africanism in the early twentieth century showed that racialized peoples, both laborers and intellectuals, were also helping to shape notions of their own identity as well as notions of where they belonged, both physically and metaphorically. While socioeconomic and political arrangements in the United States required that racialized labor forces remain fixed within the particular (material and ideological) places to which they were transported, by the middle of the twentieth century models of production and consumption instead relied upon a massive movement of these same labor forces out of their place, "from South to North in the United States, from colony to metropole in the British, French, Portuguese and Dutch West Indies, from country to city in southern and western Africa" (Holt, 2002: p. 70). This movement that was facilitated, in part, by the liberalization of US immigration laws in 1965, helped to generate a transnational wave of immigrants from homelands especially from the Caribbean, Latin America, and Asia, to new lands such as the United States, Europe, and Canada.

New Engagements of Race

By the mid-twentieth century, these changes in demographics helped to push the transformation of locally particular notions of difference into discourses of new meanings of race, ethnicity, and national descent. This reordering of human subjectivity in increasingly ethnic heritage terms follows structurally related shifts in the language of contemporary American racial organization particular to the post-1965 period. During this period, the intensification of civil rights discourses against discrimination generated new ideologies about racial/ethnic identities and racial difference. These

changes also set the stage for the formation of other postcivil rights movements that focused on honoring new cultural traditions and heritages (women's rights, gay rights, Native American rights, and Latino rights, just to name a few). In a commodified world, these new heritages, rather than becoming homogenized in an 'American melting pot' advertising discourse that stressed sameness, new marketing strategies were developed to exploit new lucrative racial and ethnic markets. The cultural formation of a new commercial politics of linkage between people in the Americas and those in related 'homelands' set the stage for the establishment of a heritage and identity category through which linkages to origins were used to supplement national identity and citizenship in the adopted country. In the social sphere, this emphasis on diasporic interconnection redefined prevalent notions of biological race to emphasize what came to be called by some researchers cultural race, shaped by new conceptions of ethnicity, or ancestral heritage (Mukhopadhyay et al., 2007; Thomas and Clark, 2006; Harrison, 2008). This notion of cultural race is also deeply rooted, not in biology but in a historical context.

During the 1980s through the 1990s, the rights discourse of the 1960s all but disappeared from the national political discourse in the United States. In other parts of the world, discourses of equality were also on the wane because states were less powerful in some locations, and in others, less willing to hold 'equality' as a value for all citizens. At the same time, the postcolonial context was one in which migration, movement, and the rise of a global media have created a situation in which as Winant has indicated "the nation-based dimensions of racial solidarity have atrophied" (Winant, 2000: p. 180). Today, no one can deny that race and racism currently exist in a world in which larger and larger percentages of national populations are illiterate, where the avenues for self-advancement have become increasingly limited, where remittances constitute ever greater percentages of developing countries' gross domestic products, where sexual tourism and sex trafficking is on the rise (in the Inland Empire of Southern California as much as it is globally), where the availability of critical social services is on the decline in the United States and elsewhere, where a commitment to social equality becomes framed as anticapitalist by the conservatives and far right politics in the United States, and where an assertive call for global peace is seen as suspiciously unpatriotic. Global economic restructuring has thus resuscitated racialized and naturalized social stratification systems that are currently at work in such industries as banking, and the mortgage foreclosure industry here in the United States that has specifically targeted poor racialized populations to prey on.

New Globalization Research and Race

It has become commonplace to speak of the contemporary intensification of processes of globalization and the ways in which they are continually reconfiguring the structures of everyday life. While scholarly analyses of globalization have proliferated, and while there have been recent attempts within the social sciences to consider the articulations among ethnicity, gender, and sexuality within a global frame of analysis, race and processes of racialization are not usually considered central to academic discussions of global economic and political transformations. Yet, globalization is facilitated by the transmission and reproduction of deeply embedded social prejudices rooted in a past characterized by territorial concepts of identity that both generated and were generated by structural racial inequalities. As such, the contemporary twenty-first century redistribution of wealth has exacerbated historically entrenched racial hierarchies. In other words, racial formations dynamically reflect and shape global processes and are not merely effects of them. As a result, the complexity of contemporary global processes can never be fully grasped without a deep understanding of the historically specific and dynamic ways that race has both constituted and been constituted by global transformations. What is clearly critical, then, to a more complete understanding of contemporary global processes is an integrated analysis of the historical precedents of current circulations, of how imperialism and racial ordering have shaped global movements, and of the ways conceptualizations of identity, membership, and citizenship have been both constructed and institutionalized in racial terms (Mullings, 2005; Thomas and Clark, 2006).

Dismantling Structural Racism: The Unfinished Job

In some ways, this short article has only touched the surface of this topic of 'race and racism' as one looks at the unfinished business of exposing anew, and then eradicating structural racism. It is not enough for researchers to just reveal the breadth and depth of the social and cultural underpinnings of structural racism, and the power dynamics that operate to maintain this highly racialized and stratified social system in US society and elsewhere. One must do more. Sociologist Howard Winant reminds us that as we talk about the issue of 'postracialism' in the United States to remember that some of the incorporative concepts of racial difference tend to actually validate the very identities they purport to question. Rather than serving as catalysts for truly new racial formations they actually "reinforce the racialized social structures such as comprehensive racial stratification, discrimination, xenophobia, etc. that they so loudly repudiate" (Winant, 2001: p. xix).

The author suggests that much more critical research and praxis work still needs to be done in key areas such as looking for new intersections in addition to mining more deeply the intersectionality of race, class, and gender; researching race, migration, and immigration both locally and globally; continued research on the validity of the claim of reverse discrimination by Euro-Americans (especially in the United States); researching the contradictions of claims of 'colorblindness' in the ubiquitous presence of conversations about race; conducting a deeper and more critical analysis of the continuing educational, housing, and health disparities along axis of race, ethnic, and class lines; researching the impact of national, regional, and state demographic changes and race; continued research and study of whiteness and power from the inside out; more research on the links between race and globalization studies; and more research on the relationship of race, gender, and human rights, just to name a few.

Conclusions

Race is about power relations, and continues to be an ideology to legitimize the dominance of certain groups. Race and its consequence racism are fundamentally part of a global system of structural racial stratification and inequality. People indoctrinated in US individualism often have difficulty understanding abstract notions of a social system, social stratification, and how one's social position impacts individual experience and opportunities. For example, fluctuations in racial categorization and definitions of 'whiteness' reflect demands for population growth set against a backdrop of powerful elites seeking to maintain a system of social stratification and cultural dominance. The US race-based system of social classification became a way of maintaining the dominance of elite 'white' groups, politically and socially, while simultaneously recruiting new populations. Race became a central basis for organizing labor and maintaining an economically stratified system, first in the agricultural sector and now in the growing industrial and postindustrial sectors. Racializing the labor force helped to mask the pervasive class stratification and structural inequality that has always characterized American life. The North American system of racial classification is most accurately viewed as a historically and culturally specific 'legitimizing ideology,' a complex and unique way for explaining, justifying, and perpetuating a system of social, economic, and political inequality. But these racial meanings were also contested in the past and will continue to be contested (Mukhopadhyay et al., 2007; Omi and Winant, 2012).

Abstract

In this article we highlight the changing geographies of race and racism, from the era of European colonialism to the present. We emphasize the co-constitution of race and space and highlight how epistemological understandings of 'race' greatly inform racist practice. Our objective in this article is to consider the legacy and malleability of racial discourse and how the construction of 'race' has material consequences. Special emphasis is placed on eugenics, racial formation theory, and critical race theory.

Introduction

To begin any conversation on race one must proceed from the standpoint that the very nature of the term is problematic (Kobayashi and Peake, 1994, 2000; Gilmore, 2002). Despite considerable efforts to 'prove' that race exists, it is now a widely accepted fact that racial differences are not rooted in any kind of biological or genetic difference, but are the result of social constructions that meet particular, economic, political, and cultural needs. Furthermore, the understanding of race in society is more often than not connected to overarching power relations. In addition, race is a geographical contextual in a process known as 'differential racialization' (Pulido, 2006). Consequently, by studying and understanding racial formation we are able to understand the sociospatial construction of space and place (cf Alderman, 1996; Holloway, 2000; Delaney, 2002; McKittrick, 2006; McKittrick and Woods, 2007; Heynen, 2009; Winders and Schein, 2013). In other words, to understand that race is a social construction is to understand not only the development of identity, but also the development of many other taken-for-granted concepts that connect to power relations (Sundstrom, 2003; Saldanha, 2006; Wilson, 2006; Inwood and Bonds, 2013).

The Birth of Modern Racial Discourse

While the identification of distinct human groups dates back to some of the earliest human writings "it was only after European explorers reached the Western Hemisphere" did any kind of "distinction and categorization fundamental to a racialized social structure" begin to appear and be used to understand human difference (Omi and Winant, 1994: 61). Thus, as European nations began to establish empires throughout Africa, Asia, and North and South America these states needed to come to terms with their conquests and to justify the exploitation of newly colonized peoples. Subsequently, there emerged an assemblage of scientific discourse that purportedly documented the natural division of humanity into a hierarchically ordered set of discrete races (Goldberg, 2002).

To place an object (such as a 'human body') in one class rather than another establishes its central characteristics and creates assumptions about matters that are not seen (Edelman, 1977: 123). This holds particularly true for the 'scientific' construction and promotion of racial categories. Out of the scientific discourses emerged (supposedly) objective criteria that purported to explain the spatial distribution and diffusion of racialized bodies. Classifications were initially constructed according to observed, yet highly selective, physical traits; these, in turn, were used to explain 'cultural' traits and behaviors, including poverty and promiscuity. In actuality, these presumed correlations worked both ways. The presumptive inferiority of 'blacks' for example (but, in general, all 'nonwhites') was taken as given and subsequently prompted the scientific search for associated morphological and anatomical signs between the 'races' (Tucker, 1994: 22; see also Miles, 1989).

While somatic differences were the most common indicator of racial difference, other measurements compared facial angles, cranial capacity, and hair texture. Other more innovative physical markers were used. Etienne Serres, for example, compared the distance between a man's navel and penis to establish differences between Europeans and non-Europeans. Even more ambitious was the work of F.G. Crookshank (1924), who attempted to establish the relationship between 'Orientals' (Mongols), the 'mentally retarded' (Mongoloids), and orangutans. As evidence, he documented differences between palm markings and hand gestures, body and limb postures, eyes, noses, teeth, arms, feet, mouths, tongues, varicose veins, brains, stomachs, anuses, and scrotums.

The 'medicalization' of 'race' afforded a significant degree of legitimacy and authority to existent racial beliefs, thus infusing them with power. Racial classifications were ordered hierarchically. Northern and western European 'races' were held as normative yardsticks against which all other 'races' were measured. The most common standard included a tripartite division of the 'white race': Nordics, Alpines, and Mediterraneans. The tall and fair-skinned Nordics (e.g., people from northern and western Europe) were thought to represent the highest echelons of humanity; lower down the ladder of civilization were the shorter and somewhat darker Alpines (e.g., people from central Europe), followed by the supposedly much shorter and darker Mediterranean peoples (e.g., people from southern and eastern Europe). Trailing behind the 'white races' were the various 'yellow,' 'brown,' 'red,' and 'black' populations.

The effort to construct (and justify) racial differences intensified as European and later North American colonies and

nations turned to the enslavement of Africans to reap incredible profits out of the lives and work of chattel slaves (Du Bois, 1935). It is important to note that chattel slavery as practiced in North America differed from the way slavery was historically understood and used in the ancient world. As a consequence early colonists and European governments went about codifying slavery into colonial societies in ways that increasingly subordinated slaves thus translating racial hierarchies into law racial that placed white men above all others. According to Du Bois (1935) the role that slavery plays in North America is central to the development of racial hierarchies not only within North America, but also within the broader Atlantic World. He argues

> Black labor [in the form of slavery] became the foundation stone not only of the Southern [US] social structure, but on Northern manufacture and commerce, of the English factory system, of European commerce, of buying and selling on a world-wide scale, new cities were built on the results of black labor.
>
> 1935: 5

As slavery began to play an increasingly important role in the spread and development of capitalism throughout the late eighteenth and nineteenth centuries, slavery is at the center of this economic development.

As national economies began to rest more fully on racially organized exploitation (e.g., slavery) and as these colonies and nations expanded it became ever more difficult to justify and rectify the needs of the nation with the exploitation of people of color (Omi and Winant, 1994: 63). Thus, "the invocation of scientific criteria to demonstrate the 'natural' basis of racial hierarchy was both a logical consequence of the rise of this form of knowledge, and an attempt to provide a more subtle and nuanced account of human complexity" (63). It is from these roots that many of our present day misconceptions about race and the continuing significance of racism emerge.

Critical for geography is the way constructed racial differences have been translated in and through space and place. For example, in North America as slavery became an ever more viable alternative to other forms of labor, laws were passed that restricted the movement of people of African descent (Delaney, 1998). Laws were also passed to prevent the so-called miscegenation of 'races' in an attempt to maintain a 'pure' racially defined society (Tyner and Houston, 2000). The legacy of these racist practices, as detailed below, continues to inform contemporary American society.

Race and Eugenics

Up through the late nineteenth century the physiological mechanisms of heredity were obscure (Paul, 1995). It was generally assumed that characteristics acquired by organisms during their lifetimes were transmissible to their progeny; such as belief was forward by the writings of Jean Baptise de Lamarck. In what became popularly known as *Lamarckism*, it was understood that animals, for example, would alter their behaviors in response to changing environmental conditions. One consequence of such changes was that certain, and selected, organs would come into or out of use (Paul, 1995: 40). When applied to humans, this 'principle of inheritance of acquired characteristics' would have direct policy relevance. Simply put, the environment in which children were born and raised would have a major bearing on subsequent generations.

By the late nineteenth century the scientific study of both heredity and (racialized) populations underwent a paradigmatic change. The publication of Charles Darwin's *On the Origin of Species* (1859), most notably, began to undermine ideas of fixed biological categories and the principle of inheritance of acquired characteristics. Darwin's work posited that humans evolved through natural laws of selection and competition. As Noel Castree (2005) summarizes, Darwin – from his expeditionary observations and his studies of pigeon-breeding – derived the metaphor of 'natural selection'; from his reading of Thomas Malthus's work on population and resources, Darwin derived the idea of the 'survival of the fittest'; and from his understanding of the work of geologists James Hutton and Charles Lyell, Darwin articulated the idea of 'deep time' – the idea that change occurs slowly over the *longue durée*. Combined, these elements suggested to Darwin that species interacted with each other and that those species best able to adapt to their conditions of existence were most likely to survive and to produce offspring similarly well adapted.

Although Darwin's theory of natural selection is in many respects counter to that of Lamarck, Darwin's theory of heredity (which he termed 'pangenesis') premised that acquired characteristics were heritable. According to pangenesis, minute particles thrown off by various cells circulate through the body and ultimately concentrate in the 'germ cells'; through this, changes in parents' bodies could be manifested in their children (Paul, 1995: 41). In opposition to the concept of the inheritance of acquired characteristics was Francis Galton (1822–1911), a statistician, naturalist, policy advocate, and cousin of Darwin. Galton premised that hereditary material was transmitted from one generation to the next. Both specific talents and traits of character and personality were inherited; so too was tuberculosis, longevity, madness, gambling, sexual passion, criminal inclinations, and alcoholism thought to be heritable (Kevles, 1995; Paul, 1995).

The mechanisms for inheritance were most clearly articulated by a German biologist, August Weismann. Throughout his writings, Weismann forwarded his theory of the continuity of the 'germ plasm.' He argued that there existed two types of cells that constituted the human body: germ cells – present in the gonads and which give rise to sperm and egg – and somatic cells, which are present in other tissues in the body. For Weismann, the germ cells (or 'germ plasm') were isolated from somatic cells; and while the somatic cells could be affected by the environment, the hereditary units of the germ plasm could not. In proposing that the germ plasm was completely independent from the rest of the cells, Weismann argued that it was the germ plasm which was inherited continuously by one generation from another without alteration from outside influences. Of significance, and in contrast to Lamarckism, Weismann's theory of germ plasm posited that environmental conditions were largely inconsequential; that no matter how much parents worked to

improve their bodies or minds, their heredity would be unchanged and their children none the stronger or smarter (Paul, 1995; see also Stepan, 1991).

By the turn of the twentieth century, scientists and social reformers had already begun to advance the idea that society should recognize the power of heredity in its social laws, in such a way as to favor reproduction of the physically and morally fit (Stepan, 1991: 26). Now, with the sustained assault against the belief in the inheritance of acquired characteristics, there appeared to be clear understanding of the task at hand. Specifically, the emerging science of genetics – buttressed by statistical and biometric studies – indicated that environmental factors played at best a minimal role in affecting the human condition.

Throughout the late nineteenth and early twentieth centuries, concern grew among the academic community that contemporary society – through charity and welfare programs – was 'tampering' with the laws of nature; that 'unfit' people were being allowed to survive and reproduce; that 'lives not worth living' constituted an unbearable financial burden on national and local budgets. These political valuations of life identified a grievous and imminent social problem and demanded an immediate solution. Fueled by Darwinian concepts of sexual selection and evolution, competing concepts of genetics, Malthusian perspectives on overpopulation, and environmental determinism, widespread fears of racial and societal degeneration permeated both popular and scientific venues. These fears were augmented by a growing – and scientifically documented – understanding of demographic changes. In the United States, for example, long-established patterns of immigration were drastically changing. Prior to the 1880s immigration was dominated by northern and western European nations; in the decades surrounding 1900, however, the main source areas shifted to southern and eastern Europe and, increasingly, Asia. Citing these changes, the labor historian and university professor John Commons (1907: 70) warned that "the change is one that should challenge the attention of every citizen."

Threats to the body-politic of the United States were not simply external. Following the abolition of slavery a moral panic ensued over the moral presence and economic position of newly freed blacks in American society. Thus, in the wake of the American Civil War, Southern politicians implemented a series of laws to retain blacks as docile, landless laborers. Known as the *Black Codes*, these laws were designed to affect white social control over black occupational, social, and geographic mobility. And while varying by state and by more local jurisdictions, the Black Codes generally denied freed slaves the right to marry whites, bear arms, or to assemble after sunset (Hummel, 1996). Unfair labor arrangements were also instituted and, consequently, African-Americans often became debt-bound to their former slave-owning masters.

Throughout the late nineteenth century – but especially during the early twentieth century, the problem of the African-American found its most forceful crystallization in the eugenic-inspired fear of sexuality. In part, (white) scientists reasoned at the time that slavery had been beneficial – from an evolutionary standpoint – to the black. Slavery, in fact, was re-presented as a form of genetic welfare, a viewpoint often reflecting a misappropriation of Darwinian thought and the process of natural selection. George T. Winston (1901: 108), President of the College of Agriculture and Mechanic Arts in North Carolina, for example, argued that slavery "transformed the Negro so quickly from a savage to a civilized man." H.E. Belin (1908: 517), writing in the *American Journal of Sociology*, concurred: "Slavery, so far from degrading the Negro, has actually elevated him industrially, mentally, and morally, the term of his involuntary tutelage [slavery] to the white race raising him to a vastly higher level than that ever occupied by his kinsmen in Africa." According to these experts, however, the abolition of slavery threatened to curtail this evolutionary improvement. The black was, on this account, retrogressing to his or her 'natural' and 'uncivilized' condition. Belin (1908: 519) described this transformation as 'frenzied,' noting that blacks who "but one brief hour before, were laughing, chattering, peaceable members of the community, are subject at any moment to be converted by some trivial occurrence into fierce, howling, blood-thirsty savages."

In short, academics and other so-called experts maintained that African-Americans, now freed from the 'beneficence' of slavery, posed direct threats to the well-being of American society. These threats, moreover, were often sexual in nature and revealed a stark-gendered component. African-American *men* posed a threat to the purity of the white race, through their supposed and unquenchable desire for virginal white women. African-American *women*, on the other hand, posed a threat also by their supposedly hypersexuality and hyperfertility. Combined, these discourses contributed to an overall image of 'uncivilized' and 'uncontrolled' blacks who retained no positive *productive* capability but considerable negative *reproductive* potential (Mencke, 1976; Hodes, 1997; Tyner and Houston, 2000).

Ongoing demographic and family studies revealed that immigrants and African-Americans exhibited higher fertility rates. If left unchecked, these reproductive trends allegedly would lead to an overall decline in the proportion of the 'original' Nordic stock of the United States. Numerous – and widely circulated – texts of the period attest to these fears: Madison Grant's *The Passing of the Great Race* (1916) and *The Conquest of a Continent* (1933), Lothrop Stoddard's *The Rising Tide of Color Against White World-Supremacy* (1920), and James Herbert Curle's *Our Testing Time: Will the White Race Win Through?* (1926).

For many 'social Darwinists' concern was raised that welfare and charity programs were tampering with the 'bloody hand' of evolution; hence, rather than succumbing to nature's law of the 'survival of the fittest,' misguided philanthropy – including minimum wages, set working hours, free public education, and public health reforms – was enabling inferior races to live longer and reproduce. Progress in the natural and social sciences – coupled with a proper political will – was required to understand both the implications of human interference on natural selection and, if possible, to provide viable methods to promote a more healthy, vital population. What was required, in practical terms, was a biopolitical control over the three fundamental processes of population change: migration, fertility, and mortality. What emerged was the eugenics movement.

As Ekland-Olson (2012: 21) writes, the eugenic argument was attractively simple: Would it not be better to have a society enriched by those who are productive, healthy, emotionally stable, and smart, than one stifled by degenerate, feeble-minded, disabled, and criminal citizens? Framed as a concern over differential worth, the eugenics movement effectively combined sexist, racist, classist, and nationalist sentiments. Indeed, as Saul Dubow (1995: 101) writes, eugenics coincided with the rising intensity of imperialist feelings, which also helped augment nationalist fervor and provide a convenient rational for the colonial subjugation of non-European peoples. Thus, as a *globalizing* paradigm, eugenics sought not only to identify differences within the human population, but also to evaluate and calculate the potential contribution of racially defined groups toward the betterment of society. As explained by the eugenicist L.H.M. Baker (1912: n.p.), "When we have ascertained … the qualities we want to preserve and the characteristics we desire to eliminate we must be courageous in the application of our remedy." From the United States to Germany, from Japan to Mexico, an array of segregation policies, immigration legislation, relocation schemes, antimiscegenation laws, sterilization, and euthanasia programs emerged as tangible – and viable – instruments in the practice of statecraft (Burleigh, 1994; Kühl, 1994). These racist practices would find their apogee in the Holocaust.

Late Twentieth- and Twenty-First-Century Race and Racism

After the atrocities of the Nazis the biological classification of race has become discredited; earlier theories of race and racial difference have been demonstrated to be themselves racist. In the years after World War II it became increasingly problematic to justify racial exploitation through pseudoscientific means. This was both a result of the atrocities of the Nazis, which justified the genocide of millions of Jewish and other European minorities, through scientifically grounded understandings of race and racism, and also because of the increasingly globalized struggle to overthrow colonial projects. The practices of colonialism came under increased pressure as global antiracist and anticolonial movements gained visibility and exposed contradictions in the old racial order (Inwood, 2013: 2122). Instead, we have now come to understand that race is not a "biologically given, but rather a socially constructed way of differentiating human beings" (Omi and Winant, 1994: 65) that nonetheless has real and meaningful consequences for society. The question then becomes, how do we come to understand race and why do we continue to live with and through the consequences of racism? The simple answer is because the discourse of race (and racism) is not profitable, it continues to reinscribe hierarchies that reinforce and retrench historic practices of exploitation. How, one might ask? While the answer is complex the social sciences have increasingly turned to questions of 'systemic racism' to address the continuing significance of race.

For the past quarter century understandings of race and racism, particularly in a North American context, have been dominated by the work of Omi and Winant (1994) and their seminal work on racial formation. Omi and Winant argue that to understand race one must focus on the link between "structure and representation" the way "racial projects do the ideological work of making links" between these two positions (1994: 56). They argue we should view race and racial formation as a sociohistorical process in which race and concomitant racial categories are created, transformed, or destroyed depending on contemporary political and economic necessity. Critical for understanding their argument is the way racial ideology is dialectically linked to social structure and the ways these relations come "to shape the nature of racism" (Omi and Winant, 1994: 74).

Recently this approach to racial formation has been challenged by critical race scholars who argue that we need to place racism more centrally into analysis of race (Chari, 2008). This argument has been made most forcefully, and some would argue persuasively, by the work of Joe Feagin and Sean Elias, among others (cf Feagin, 2006; Feagin and Elias, 2013), who argued that we need to focus more intently on 'systemic racism approaches.' Systemic racism critiques argue

> the past and present racial hierarchy and perpetuation of unequal socio-economic power relations among different groups are viewed as endemic to a race-based social system involving much more than conceptual meanings, ideologies and biased actions. In the case of US society, systemic racism is foundational to and engineered into its major institutions and organizations.
>
> Feagin and Elias, 2013: 936

Systemic racism approaches begin from the premise that racism and racial stratification have operated for centuries and, while sociospatially contingent (Pulido, 2006; Chari, 2008), have consistently reinscribed historic racial hierarchies. Systemic racism approaches argue that it is only through the consideration of racial oppression that we can begin to understand the true nature of race (Golash-Boza, 2013). In so doing a 'diverse assortment of racist practices' becomes readily evident including the unjustly gained economic and political power of whites; continuing resource inequalities; the rationalizing white racist frame; and the major institutions created to preserve white power and advantage (Feagin, 2006).

What is central to this approach is that the focus of critical race scholars needs to be on the ways the "recurring and unequal relationships between groups and individuals" (Pulido, 2006: 13) are continuously made and remade through time and space. In other words, and what makes systemic racism approaches relational to critical geography, is the way racism is understood as being dialectically linked to other social, economic, and political systems in the US (and elsewhere) and the way those systems perpetuate white racial rule (Peake and Schein, 2000). In taking such an approach we can more fully come to terms with the reality that white supremacy is a permanent fixture of life in many parts of the world. The continuance of white supremacist and neo-Nazi groups in France, Germany, Italy, and the United Kingdom is testimony to the perniciousness of an inherited legacy of virulent forms of racism and racial violence (cf Blee, 2005).

Racism and racial violence however need not be so apparent. Over the last quarter of a century there has been

a transformation of racism to subtler and more covert manifestations of white supremacy (Coates, 2008; Finney, 2013). Such practices have in large part been aligned with the penetration of neoliberalism. As Berg (2012: 511) argues, neoliberalism "produces an epistemological space in which humans are all the same (the so-called 'level playing field') and – ironically – where to even raise the specter of 'racial difference' is itself read as an act of racism." Berg (2012: 511) continues that the attempt to erase 'race' has a long history; what is distinctive to neoliberalism is that "certain forms of difference are highlighted, but others are effaced." In the maelstrom of neoliberalism, consequently, has emerged the discourse of 'postracialism' and the concomitant claim that North American and European societies are becoming 'race-blind' or 'color-blind' (Haney-López, 2010). Within the United States, the recently enacted Matthew Shepard and James Byrd Jr. Hate Crimes Prevention Act of 2009, signed into law by Barack Obama, America's first African-American president, seems to confirm what a number of political pundits – both liberal and conservative – have been arguing: that American society has entered into a postracial era. The term 'postracial,' in this context, encompasses the idea that if racial attitudes today are the same as they were in the last few decades, then it would have been impossible, for example, that the Hate Crimes Prevention Act would have been signed into law; or that Obama would have been elected. According to this view, therefore, the United States has finally transformed from a place where racial slavery and segregation were legally sanctioned and commonplace practices, to a place in which the American people could put aside their racial prejudices and unite to elect a president of African origin (Young, 2012: 501).

Despite such claims, or perhaps because of these claims, the malignant effects of racism have not abated. If anything, racism has intensified – albeit disguised in part by coded language that is not necessarily amenable to either empirical study or criminal prosecution (cf Coates, 2008). Perhaps as a result over the last three decades critical race theory (CRT) has become a dominant paradigm in the study of race and racism (Price, 2010).

Critical race studies is related to the development of CRT that emerged during the 1970s from the work of legal scholars Derrick Bell and Alan Freeman who were frustrated over the 'slow pace of racial reform' and wanted to understand the way race was reproduced in the US legal system (Delgado and Stefancic, 2000: xvi). Since that time, CRT has evolved to encompass a variety of academic disciplines and incorporates a wider critique of the processes involved in sustaining systems of racial oppression in the United States (Lynn et al., 2002). CRT leads to a shift in our understanding of racism from "willful acts of aggression" to "discussions of [the ways] race and racism are deeply embedded within the framework of American society" (Parker and Lynn, 2002: 8). CRT posits that "racism is normal, not aberrant in American society" and argues that current efforts at addressing racial injustices only "remedy the more extreme and shocking forms of injustice," noting that more subtle forms of racism are almost impossible to address using current legal and economic solutions (Delgado and Stefancic, 2000: xvi). The overarching goal of CRT is to "expose the historical, ideological, psychological, and social contexts in which racism has been virtually declared to be eradicated" and instead to show how racism is still a fundamental organizing principle in society (Parker and Lynn, 2002: 10). Those who adopt a CRT approach frequently (1) recognize that race is a social construction and argue for the eradication of racism; (2) draw important relationships between race and other axes of domination, thus illuminating the way racism links with other forms of injustice; and (3) present narratives and other qualitative approaches as valid approaches through which to examine race and racism (Parker and Lynn, 2002: 10).

Critical race studies integrate concepts from CRT through an integrative, qualitative methodology. Critical race methodology (1) foregrounds race and racism in all aspects of the research process; (2) challenges traditional research paradigms used to explain the experiences of persons of color; (3) offers transformative solutions to racial, gender, and class subordination; and (4) focuses on the *experiences* of persons of color (Solorzano and Yosso, 2002: 24). Critical race methodology seeks also to integrate these goals by emphasizing counter-narratives (Milner, 2008; Solorzano and Yosso, 2002; Delgado, 2000). Montecinos (1995) for example argues that the ideology of racism works through the use of master narratives which justify and maintain systems of oppression. Nash (2003: 639) similarly argues that research informed by a critical race studies perspective offers the field of geography a number of useful research tools to address the "multi-scaled processes that shape the lives of racialized groups" and invites the "bridging of perspectives across economic, cultural, urban, social and political geography" (639).

This article is a revision of the previous edition article by R.T. Ford, volume 19, pp. 12684–12689, © 2001, Elsevier Ltd.

Abstract

This article examines the use and treatment of race in the legal systems of several countries, including the use of racial categories in case law, statutes, and constitutional texts and the influence of racial politics on the development of law. It addresses the historical use of racial criteria for immigration and naturalization, racial apartheid, and 'Jim Crow' laws. It also discusses the statutory and constitutional prohibitions against racial discrimination, legal and policy initiatives to promote racial integration, and contemporary debates surrounding affirmative action and racial categories. It compares and contrasts the laws of the various nations whenever relevant comparison is useful and will attempt within the limitations imposed by length to provide a snapshot of the development of the legal treatment of race worldwide.

Definition of the Field

The study of race and the law is primarily, but far from exclusively, occupied by scholars trained in law and working in law schools. In Canada and Europe, the field is more evenly divided among lawyers and social scientists trained in anthropology, sociology, and cultural studies.

Mainstream versus Critical Scholarship

Scholarship addressing race and the law is split between mainstream approaches and critical approaches. Mainstream approaches generally conceive of racial discrimination as a minor and isolated exception to the otherwise liberal and enlightened societies of the industrialized West. These scholars understand racial injustice as largely unconnected to other institutions and are therefore optimistic that racism can be eliminated 'surgically,' without requiring significant or widespread changes in society. This is not to say that mainstream scholarship is always sanguine about the prospect for successful antiracist policy, but it tends to look at such policy as an isolated policy intervention that need not affect the basic institutions of the market economy or the majoritarian political process. Critical scholarship, by contrast, understands racism as deeply implicated in the institutions and traditions of societies and is therefore accordingly both more radical in its prescriptions and more circumspect in its predictions of success (Bell, 1987; Crenshaw, 1995; Williams, 1991).

Because the definition of race is malleable, fluctuating, and contested, the study of race and the law encompasses not only 'race' as it is colloquially understood, but also issues of ethnicity, national origin, caste, and religious and cultural differences. The field could therefore be understood to include the study of ethnic and nationalist divisions in Asian countries, caste hierarchy in Hindu societies, tribal conflict in central Africa, and religious conflict worldwide. It implicates the study of nationalism and pannationalist movements, communities of diaspora, and indigenous peoples. Moreover, the field is deeply concerned with the ways that race intersects with issues of gender, sexual orientation, and class (Crenshaw, 1995; Harris, 1990; Thomas, 1995; Williams, 1991; Carbado, 1999; Banks, 2010).

Generally speaking, the study of race and the law encompasses two major projects. The first is a critique that demonstrates how legal institutions and formal laws produce and perpetuate racism and racial hierarchy. The second is the analysis of legal reform that might eliminate or minimize the effects of racial hierarchy. This article will address each in turn.

Law as a Cause of Racism

Legal scholarship addresses the various ways in which law has produced and continues to produce racial hierarchy. Law contributes to racism and racial hierarchy in at least three distinct ways. First, it codifies racial categories, which are then employed by both public and private actors to erect and maintain racial hierarchies. Second, law institutionalizes racial hierarchy by creating formal rules requiring or encouraging racial hierarchy: by segregating the races; by excluding the members of certain races from participation in social, economic, and political activities and institutions; or by legally codifying the subordinate status of one or more races. These first two types of legal action are commonly known as *de jure* racial discrimination because they explicitly employ or create racial categories by force of law. Third, law allows, encourages, and requires the maintenance of institutional practices and social customs that perpetuate racial subordination by entrenching the racial hierarchies of the past, even when no formal legal rule requires or promotes racial subordination on its face. This latter type of legal action is known as *de facto* racial discrimination because it in fact produces and enforces racial subordination, although it does not do so explicitly.

Racial Categorization

Many scholars have studied the development and use of racial classificatory schemes (Davis, 1991; Haney-Lopez, 1994; Omi and Wynant, 1994). Virtually all scholars agree that, historically, schemes of racial classification were not based on sound scientific theories and therefore do not reflect any 'real' biological differences between the races. Given the dubious scientific basis for any racial classification of human beings, it is not an exaggeration to assert that law not only enforced racial hierarchy, but it also (along with other social institutions and practices) in fact produced a specific type of racial difference.

The Ontological Status of Racial Categories

There is disagreement about the ontological status of racial categories and the centrality of law in producing racial categories. Some scholars believe that racial categories have a substance that predates or transcends legally enforced and encoded racial categorization. While few scholars would argue that races are well understood in terms of biological or genetic difference, many argue for or assume that cultural differences distinguish the races (Gotanda, 1995; Peller, 1995). The belief that racial categories describe an essence or positive (in the sense of 'positive science,' not necessarily in the sense of 'good') attribute of human beings – whether biological or cultural – is known as racial essentialism.

Other scholars argue that social practices, including legal codification, produced racial differences where there were no such differences before. These scholars contend race as not an attribute of individuals or groups but instead the effect of a social or legal discourse that ascribes difference to individuals and groups (Appiah, 1996; Haney-Lopez, 1994). They insist that without the discourse of race, there would be no races. The belief that race is not an attribute or essence of individuals or groups but is instead the effect of the social discourses that describe it and the social practices that make it relevant is known as antiessentialism or social constructivism.

The Legal Codification of Racial Categories

Legal historians have examined the development and transformation of racial categories and definitions. A vast literature details the variety of racial classificatory schemes employed in the USA, Europe, and South Africa. The contemporary literature is overwhelmingly critical of most racial categorization, both because of its opportunistic use of scientific data (or its use of questionable science to justify racial categories) and the oppressive use to which racial categories have been put.

There is, however, some dissension on the question of remedial or the so-called benign racial classification. A widespread understanding of constitutional law and a pervasive popular attitude hold that the legal codification of *any* racial classification is socially deleterious and morally indefensible (Thernstrom and Thernstrom, 1999). This view asserts that the law should be *race blind*. Many scholars who may not insist on strict color blindness nevertheless have serious misgivings about the use of racial classifications, even for remedial purposes (Carter, 1991). Others believe that racial classification is not per se undesirable and argue that remedial racial classification is the necessary antidote to centuries of oppressive racial classification. They assert that the law should be affirmatively *race conscious* (Crenshaw, 1995; Gotanda, 1995; Matsuda and Lawrence, 1997; Peller, 1995).

The Legal Enforcement of Racial Hierarchy

Along with the study of racial categorization, a core concern of the study of race and the law is the legal enforcement of racial hierarchy. Of course the two are closely related: racial categories developed hand in glove with policies of racial exclusion, segregation, disenfranchisement, and involuntary servitude. The study of racial hierarchy has traditionally distinguished between formally enforced racial distinctions, hierarchies, and exclusions – *de jure* racial practices – and the formal requirement and enforcement of practices that have the effect of establishing or perpetuating racial hierarchy – *de facto* racial practices.

De Jure *Racial Subordination*

Legal historians have detailed the legal mechanisms that historically have enforced and perpetuated racial hierarchy. Historians of the USA study the institution of racial hierarchy through chattel slavery (Tushnet, 1981) and the post-emancipation development of 'Jim Crow' laws, which required racial segregation in public institutions and accommodations such as school restrooms, drinking fountains, eating facilities, railroad coaches, and theater or stadium seating (Woodward, 1989). Similar if less comprehensive policies targeted Asian-Americans (Kang, 2008; Carbado and Moran, 2014) and Hispanics (Carbado and Moran, 2014). Scholars of South Africa study the emergence, transformation, and eventual dismantling of racial *apartheid*, a policy that codified a belief in black inferiority as explicit policy and required segregation of the races in virtually every aspect of political and social life (Goldberg, 1994). Comparative scholars analyze the difference and similarities of South African apartheid and American Jim Crow laws (Ford, 1999; Goldberg, 1994).

Much of the historical study of European racial policy takes place as part of the study of European colonialism (Appiah, 1993; Bhabha, 1994; Gilroy, 1991; Ruskola, 2013). Explicit colonial racial policy and the treatment of non-whites in Europe are understood to implicate the ideology and political economy of European colonial rule (Ruskola, 2013). Scholarship concerning contemporary issues addresses the treatment of migrants, religious minorities, and non-whites who trace their ancestry to former colonies. Comparative study looks at differences and similarities between the racial policies of different nation states; for instance, studying how the American antiracist policy has been shaped by the experience of slavery and Jim Crow while European antiracist policy has been influenced by the atrocities of World War II (Suk, 2007). The question of religious intolerance, especially with respect to Muslims, is a topic of significant concern; many commentators suggest that Muslims are 'racialized' in much of Europe and the United States (Scott, 2010).

De Facto *Racial Subordination*

Formal racial exclusion, segregation, and hierarchical classification are rare in the postindustrial mass democracies of today. They have been rejected by mass opinion, eliminated by legislation, and struck down by courts applying constitutional law and international law. Nevertheless, racial hierarchy persists as a significant feature of every society with a history of racial differentiation. Accordingly, the study of race and the law focuses a significant amount of attention on informal or implicit practices that effectively perpetuate racial hierarchy.

The focus on *de facto* racial subordination began as a response to racial practices in the postcivil war USA. Federal constitutional guarantees of emancipation from slavery, equal protection, and the right to vote prohibited certain explicit racial barriers (*see* Civil Rights; Civil Liberties and Human Rights; Rights: Legal Aspects). But many states, especially

those of the former confederacy, found mechanisms to effectively reestablish these racial barriers without explicit reference to race. For instance, although blacks had a formal right to vote, many states effectively eliminated the black franchise through poll taxes and literacy requirements that were informally waived or ignored for whites but strictly enforced against blacks. And despite the formal emancipation of black slaves, many blacks were effectively forced into perpetual indentured servitude through the notorious sharecropping system of Southern agriculture (Goluboff, 2010; Klarman, 2004).

Informal and *de facto* forms of racial subordination emerged again as the response to more comprehensive civil rights reforms of the Civil Rights Act of 1964. Significantly, the Civil Rights Act prohibited racial discrimination in employment and accommodation in private institutions such as hotels, restaurants, and theaters, and in the sale and rental of housing (*see* Civil Rights; Civil Liberties and Human Rights; Rights: Legal Aspects). Many of the private institutions covered by the Act sought effectively to reproduce racial exclusion or discrimination through less explicit means. Lawyers, activists, and scholars, armed with a knowledge of postcivil war history, were able to identify and critique these practices (Dudziak, 2000; Mack, 2012). The attack on *de facto* racial subordination and discrimination became a staple of civil rights litigation as scholars and lawyers worked to expose the variety of practices that effectively perpetuated racial subordination. Antiracist scholarship and legal practice have attacked a host of formally color-blind practices as effectively racially discriminatory, including electoral gerrymandering (Guinier, 1994), standardized tests (Matsuda and Lawrence, 1997), neighborhood schools in a context of racially segregated neighborhoods (Ford, 1995; Denton and Massey, 1993), restrictive land use regulations (Ford, 1995; C. Harris, 1995), informal racial steering in real estate sales, municipal boundary formation (Ford, 1995, 1999; Anderson, 2010), and informal racial discrimination in hiring and promotions (Wilson, 2010; Ford, 2008).

Antiracist Legal Reform

Scholarship that examines, analyzes, and advocates the development of antiracist legal reform encompasses a vast range of proposals and is based on a number of methodologies and ideological commitments. Many approaches to antiracist reform build on civil rights reforms of the 1960s in the USA, advocating the expansion of such reforms and or the adaptation of such reforms in other national contexts (*see* Civil Rights; Indigenous Rights; Sexual Orientation and the Law; Law and People with Disabilities for information about how these paradigms have been applied in other settings).

A significant split has emerged between mainstream and critical approaches. Critical approaches question the efficacy and the underlying ideologies of mainstream civil rights and liberal antiracism (*see* Critical Race Theory). Beginning from an analysis that sees the problems of racism as deeply imbedded in the structure of social practices and institutions – including law itself – critical approaches are skeptical of reform proposals that attempt 'surgically' to correct or ameliorate racial bias while leaving most institutions and social practices more or less unchanged (Bell, 1987; Crenshaw, 1995). Nevertheless, many critical approaches often build on mainstream reforms, arguing for their radical expansion (Matsuda and Lawrence, 1997; Williams, 1991). Others suggest that mainstream reforms do more harm than good and should be abandoned altogether in favor of more comprehensive changes (Tushnet, 1984). Still others argue that while mainstream civil rights can play an important part in reducing racial bias, they are both insufficient and subject to abuse (Kelman and Lester, 1997; Ford, 2008, 2011).

Integrationism; Separatism

Crudely put, antiracist legal reform is characterized by a split between two strategies and or normative commitments, one which favors the integration of the races and another which favors the development of distinct, autonomous, and separate communities (Peller, 1995).

Historically, racial hierarchy has been legally enforced through spatial quarantine: American Jim Crow laws enforced the physical separation of the races in public accommodations and state institutions; racial zoning and restrictive covenants have divided the metropolitan landscape into racial neighborhoods; South African apartheid enforced racial segregation on a comprehensive regional scale and imposed racially specific curfews in white-only jurisdictions. Spatial segregation not only had potent symbolic consequences but also facilitated the inequitable distribution of resources: white-only institutions were consistently better situated, better funded, and socially and politically privileged compared to those assigned to racial minorities.

Given this history, a significant approach to remediation has been to encourage the integration of the races in public and private institutions and residential environments. Many American civil rights reformers believed that antiracist legal reform should embody a positive preference for integration *qua* integration (Wilson, 2010). Others believed that integration was desirable only because it would undo or stymie the inequitable distribution of resources in a society. These two rationales for integration produced a powerful consensus that has dominated American civil rights discourse since the 1960s and which has been influential in many other national contexts (Sabbagh, 2007; Bleich, 2003).

At the same time, however, a competing view has held that the development of distinctive and empowered minority communities is essential to racial justice and equality (Peller, 1995). This view focuses on the need for political solidarity, social support, and cultural autonomy. Racial 'separatism' has grown in popularity as many racial minorities have become disillusioned with the limitations of mainstream civil rights and the difficulties and compromises entailed in integration.

Antidiscrimination

A dominant conceptual and practical approach to antiracist legal reform has been that of antidiscrimination. The antidiscrimination concept presupposes that racial hierarchy is the result of irrational prejudice or bigotry based on race. Therefore, legal reform should prohibit intentional racial

discrimination and practices and some policies that disparately impact members of racial minority groups. The anti-discrimination approach focuses on specific wrongful actions by identifiable decision makers: if no wrongful act can be identified, there is no legally cognizable or remediable harm (see Freeman, 1995; Equality and Inequality: Legal Aspects).

Antisubordination

An alternative approach to antiracist legal reform is that of antisubordination. The antisubordination approach views racism as a set of practices that have the effect of systematically reproducing racial hierarchy, even if no identifiable decision maker can be said to be racially biased. Antisubordination approaches therefore insist that practices that adversely affect racial minorities should come under legal scrutiny, even in the absence of evidence of intent or bias. More importantly, antisubordination approaches look for patterns and systems in which several distinct practices combine to produce regular, predictable, and systematic racial subordination even when each individual practice, viewed in isolation, might seem unproblematic (Crenshaw, 1995).

Implicit Bias

Social psychologists have argued that individuals may harbor and act on biases of which they are unaware (Banaji and Greenwald, 2013). Such 'implicit' or unconscious biases are prevalent in many societies and can lead to discrimination in employment, law enforcement, and other social interactions. Some legal scholars have argued that implicit bias has important implications for antiracist law reform (Krieger, 1995; Kang, 2012). Others question the social science underlying claims of implicit bias (Arks and Tetlock, 2004) and/or its importance for civil rights law (Banks and Ford, 2009).

Cultural Discrimination

One significant strand of antiracist politics seeks to advance a project of racial recognition or multiculturalism, emphasizing the distinctiveness of racial minority communities in terms of culture. This strand seeks legal reform prohibiting discrimination against the cultural practices of racial minority groups as well discrimination on the basis of race *qua* status (Gotanda, 1995; Peller, 1995; Kymlicka, 2001; Carbado and Gulati, 2013).

This approach can be understood as a logical extension of the antisubordination approach to antiracist legal reform: discrimination against cultural practices effectively harms members of racial minority groups and can be seen as a component of systematic racial subordination.

One necessary consequence of racial multiculturalism is that it requires a definition or widely shared understanding of the content of racial identity or a racial culture. Such understandings or definitions are often controversial, both in society at large and within the given racial group itself. Moreover, the idea that racial identity or culture exists in a static or stable form is itself controversial. Some scholars would reject the very idea of a static or widely shared understanding of racial identity or culture as mistakenly essentialist (see Section The Ontological Status of Racial Categories).

Criminal Justice

Especially in the United States, racial disparities in the administration of criminal justice has long been a topic of scholarly and political concern. Legal scholarship has focused on racial disparities in the application of capital punishment, length of sentencing, and frequency of conviction (Kennedy, 1998). American prisons have been described as a new form of Jim Crow segregation (Alexander, 2010) and advocates have called for significant reforms ranging from the repeal of drug laws that disfavor minority groups to protest movements urging juries to refuse to convict minority defendants (Butler, 2009).

Antiessentialist and Cosmopolitan Conceptions of Racial Identity

A strand of antiracist scholarship first articulated within postcolonial African, Caribbean, and Indian communities that approach racial identity as fluid and supple, yet also the source of rich political, social, and cultural affiliations. These approaches define racial identity not in terms of a biological or cultural essence, but instead in terms of identification (Appiah, 1996; Bhabha, 1994; Gilroy, 1991; Ford, 2005). According to one strand of this scholarship, members of racial minority groups share common 'passions' based on shared or analogous experiences of racial subordination (Gilroy, 1991). This approach dispenses altogether with any remnant of biological or inheritance notions of racial identity: members of what might traditionally have been several different 'races' can and do share a cosmopolitan racial identity that can transcend national boundaries, cultural traditions, skin color, and phenotype. This scholarship adopts an explicitly antisubordination approach to anti-racism, but rejects the multiculturalist focus on cultural traditions within distinctive racial or ethnic communities as traditionally defined (Ford, 2005). Recent scholarship looks to a future of more complex race relations as racial mixing and new forms of 'racialization' change the nature of racial identity, create new racial categories, and perhaps even alter the conventional understanding of the concept of race (Hochchild et al., 2012).

Abstract

This article reviews the relationships among ethnicity, race, and health, based largely on populations located in the United States. Key indicators of health, including life expectancy, infant mortality, and specific disease incidence, vary by race and ethnicity. While improved medical care efforts have contributed to dramatic increases in life expectancy, the health status gap between majority and some minority racial and ethnic groups continues. Racism and economic deprivation underlie many of the observed racial variations in health. Understanding the interrelationships of race, ethnicity, and health requires identifying health-enhancing and health-damaging characteristics linked to socioeconomic status, race, and ethnicity.

This article provides an overview of the relationships among ethnicity, race, and health, based largely on populations located in the United States. The available data indicate that key indicators of health, including life expectancy, infant mortality, and specific disease incidence, vary by race and ethnicity. While people with higher income levels and more education live longer and experience lower levels of infant mortality, racial differences remain even within these higher income levels. Numerous research studies lead to the inevitable conclusion that racial and ethnic statuses are conspicuously related to the prevalence of disease and death (Smedley et al., 2003; Murray and Woods, 2009). Although improved medical care and prevention efforts have contributed to dramatic increases in life expectancy in the United States, the health status gap between majority and some minority racial and ethnic groups remains unchanged (NCHS, 2007).

In racially stratified societies, institutional discrimination linked to both historical and present racism and economic deprivation has resulted in large racial differences in socioeconomic status (SES). In turn, these variations in SES underlie many of the observed racial variations in health. In addition, racism can directly affect health through racial bias in medical and other service agencies and institutions and lead to the development of stress associated with experiences of discrimination and the acceptance of negative societal stereotypes. Advancing our understanding of the role of race and ethnicity in health thus requires better data that can identify the ways in which health-enhancing and health-damaging characteristics linked to SES, race, and ethnicity relate to each other and combine to affect health.

What is Race and Ethnic Status?

Historically, race has been viewed as capturing biological variation within human populations. However, the concept has never rested on a firm, scientific foundation. The delineation of racial taxonomies predates our understanding of genetics (Keita et al., 2004; AAPA, 1996). Thus, race emerged as a sociopolitical construct, useful to justify the exploitation of groups defined as inferior as well as to classify phenotypic variations in the population (Perry, 2011). Historically, the conceptualization of race has been influenced by cultural and political considerations, and race has served important ideological functions in society (AAPA, 1996). For example, medical research in the nineteenth century attempted to document that blacks were biologically inferior to whites and therefore more susceptible to a broad range of diseases. Importantly, such analyses provided a scientific justification for slavery and economic exploitation (Harawa and Ford, 2009).

Understanding and addressing the role of race and ethnicity in health requires a clear understanding of what race and ethnicity are, as well as the identification of the specific risk factors and resources linked to racial and ethnic status that may be responsible for variations in health. A growing body of evidence indicates that the traditional conceptualization of race is flawed. Scientists at the National Institutes of Health, after writing a draft of the entire sequence of the human genome, unanimously declared, that there is only one race – the human race (Angier, 2000; NCHPEG, 2014). Our current racial categories are more alike than different in terms of biological characteristics and genetics, and there are no scientific criteria to classify the human population unambiguously into discrete biological categories with rigid boundaries. Thus, racial taxonomies are arbitrary, and race is more of a social construct than a biological one.

Although ethnic groups can share a range of phenotypic characteristics due to their shared ancestry, the term 'ethnicity' is typically used to highlight cultural and social characteristics rather than biological characteristics. Ethnic groups share some combination of common geographic origins, family patterns, language, common values, cultural norms, religious traditions, literature, music, dietary preferences, and employment patterns. Thus, the current 'racial' categories often capture the essence of ethnic variation that is reflective of common ancestry, history, and/or culture.

Some writers have suggested that the term 'ethnicity' should replace 'race' in health research, and the term race should be abandoned (Afshari and Bhopal, 2002). However, although not useful as a biological category, race is an important social category. It is what sociologists call a master status – a central determinant of social identity and obligations, as well as of access to societal rewards and resources. Given that racial categories have reflected racism and its consequences (oppression, exploitation, and inequality) historically, collecting the appropriate data on race can facilitate ongoing monitoring of the magnitude of differentials and enhance understanding of

their causes and the development of effective interventions to address them.

Relatedly, even though variations in health are evident for many ethnic groups, much of the marked variation is evident for minority racial and ethnic groups. The term 'minority' is not used to represent the numerical size of a population, but rather the historical castelike status and lack of access to power and resources of that group. The current 'minority' groups in the United States, for example, reflect the intersection of racial and ethnic status combined with economic disadvantage. The groups that experienced discrimination historically and have been unsuccessful in assimilating are often termed 'minority' groups.

The Challenge of Analyzing Health Data

Data from the United States also suggest that there is considerable inconsistency in reporting racial, and especially ethnic, status over time. Given that many persons are multiracial or multiethnic in ancestry, self-identity appears to be importantly linked to the particular context of measurement. Categories of race and ethnicity are often assessed differently across societies, over time within particular societies, and by different agencies and institutions even within the same society. In the United States, for example, the standard birth and death certificates were revised in 1989 to include identifiers for Hispanic status. But the wording of the question assessing Hispanic status varies from state to state, and the data on Hispanic ethnicity is not completely reported in all states. Similarly, many health surveys and federal data collection systems in the United States use one question to assess race and a separate one to assess Hispanic origin, while other agencies use one combined question to assess both racial and ethnic status. Importantly, differing wording of racial and ethnic questions will provide varying estimates of the size of racial/ethnic populations.

Concomitantly, there is considerable debate over the optimal terminology to be used for particular racial groups, the number of racial groups for which data should be collected, the boundaries between racial and ethnic status, and whether new categories should be developed for persons who are of mixed ancestry. For a growing number of persons in society, racial and ethnic status is not singular and static, but multiple and dynamic. For example, current US census data uses the term 'Hispanic' to describe persons who identify themselves as 'Latino,' 'Mexican,' 'Mexican-American,' 'Chicano,' 'Cuban,' 'Puerto Rican,' and South or Central American, as well as persons who consider themselves to be of another Hispanic, Latino, or Spanish origin. Hispanics can be of any race, and prior to the 1970 census in the United States, were all categorized either as 'white' or as any other racial designation they chose. In addition to these dynamic classifications, the fastest growing racial designation in the United States is 'mixed race' (Associated Press, 2009).

Racial and Ethnic Variations in Health

Across a broad range of societies, racial and ethnic statuses predict variation in health. The United States has routinely reported health statistics by race, and the role of race and ethnic status is readily evident in US data. National mortality data reveal that blacks have higher death rates than whites for 4 of the 15 leading causes of death in the United States (NCHS, 2010). Cardiovascular disease is the number one cause of death for all groups except Asians, for whom cancer is the most frequent cause of death. Blacks have higher rates of death than whites from diabetes, kidney disease, infection, and human immunodeficiency virus, and the highest rate of death by homicide. Hispanics and American Indians have lower mortality rates than whites for cardiovascular disease and cancer, but higher rates for some causes of death, such as diabetes and liver disease. In contrast, the Asian/Pacific Islander population has higher mortality rates from cancer and cerebrovascular disease than other groups, but slightly lower mortality rates than whites or blacks from cardiovascular disease (NCHS, 2010, 2012).

Internationally, there are marked differences in health status between developing countries and economically developed countries. In part, it appears that these differences represent disparities in access to health care, as well as access to adequate and healthy food and water. The research associated with the Preston curve, which demonstrates a strong relationship between life expectancy and the level of economic development, reveals that even advances in medical technology do not eliminate the differences between rich and poor countries (Bloom and Canning, 2007). **Table 1** illustrates the differences in life expectancy and infant mortality rates in several countries from the developed and developing worlds. On the whole, developing countries have shorter average life expectancies and higher infant mortality rates than economically developed countries.

Very few countries collect health statistics on their constituent ethnic groups. For example, until recently, the United Kingdom did not focus on racial/ethnic variations in health. However, analyses of death rates by country of birth suggest that there may be important racial/ethnic variations in health status in England (Balarajan and Raleigh, 1995). These patterns are complex and vary by both the specific ethnic group and health outcome under consideration. Another example is that the death rate from coronary heart disease and stroke is higher

Table 1 Life expectancy and infant mortality rates per 1000 in selected countries in the developed and developing world

Country	*2012 Male/female life expectancy*	*2012 Infant mortality rate*
United States[a]	76.0/81.0	5.9
France	78.3/84.7	3.3
Japan	80.6/87.4	2.2
United Kingdom	78.5/82.4	4.5
Canada[a]	78.8/84.2	4.8
Mexico	72.9/77.6	16.8
India[a]	66.8/68.3	46.1
Botswana	56.9/54.5	10.5
Brazil[a]	69.2/76.5	20.5
Egypt	70.3/75.7	24.3

[a]Indicates a country with a substantially (25% or more) racial or ethnically diverse population.

than the national average for persons from the Indian subcontinent and the African commonwealth. The experience of the United States and England is not unique. In a comprehensive review of racial and ethnic differences in disease internationally, Polednak (1989) reveals that racial and ethnic status predicts variations in health across a broad range of societies.

Socioeconomic Status: A Central Determinant of Health

Although racial and ethnic status does not tell us much about underlying biological risks for disease, they often reflect SES. SES has traditionally been defined as a composite of education and income, which are in turn closely correlated. Low levels of education are correlated to lower income levels, and persistently low income levels are most often found among ethnic and racial minorities. In many, though not all cases, low-SES populations experience poorer health outcomes, including lower life expectancy, higher infant mortality, lower rates of health insurance or access to health care, and higher rates of death from particular illnesses. Thus, racial and ethnic differences in SES are central to understanding health status variations.

Disadvantaged racial/ethnic groups, such as the Maori in New Zealand, blacks in South Africa, and aboriginal populations in Australia, have higher rates of disease than the more advantaged groups within their societies. For example, in South Africa, despite the dismantling of the apartheid system, the infant mortality rate was three times higher for blacks and 2.3 times higher for Coloureds than for white infants (Burgard and Treiman, 2006). There are a few exceptions; Muslim babies in India have a lower infant mortality rate than the general (mostly Hindu) population, even though the Muslim population has considerably lower incomes and educational levels (Dutta and Chandrashekhar, 2012).

Racial Differences in Socioeconomic Status

There are important differences in power and SES across major racial and ethnic groups in the United States and in other countries. In the United States, the relationship between income, race, and education is clear, as shown in **Table 2**. As the table indicates, groups with fewer bachelor's degrees have lower incomes, and Asians, who have the highest percentage of persons holding at least a bachelor's degree, have the highest income levels. However, within the United States, some Asian subgroups such as the Hmong, Laotians, and Cambodians, have lower levels of income and higher rates of poverty than the black or the American Indian populations. This highlights the heterogeneity that exists within many of the major racial and ethnic categories, and the importance of attending to the variation within the subgroups of which large racial and ethnic categories are composed. For many racial/ethnic groups, an overall statistic masks the variation in health status and outcomes that exists for subgroups within that population. In addition, racial differences in income understate the true magnitude of racial differences in economic circumstances.

Table 2 Median family income and percent with at least a bachelor's degree of racial and ethnic groups in the United States in 2009

Race/ethnicity	*Income*	*% With at least a bachelor's degree*
All races	60 088	31
White	104%	35
Black/African-American	64%	21
Hispanic/Latino	66%	15
American Indian	63%	13
Asian	124%	51

Source: United States Census, 2012. Money Income of Families – Median Income by Race and Hispanic Origin, Detailed Years of School Completed by Persons 25 and Older by Sex, Race and Hispanic Origin. American Fact Finder.

In US census data, income captures the flow of economic resources into the household. In contrast, wealth reflects the accumulated economic reserves that can cushion a decline in income and facilitate long-term planning. Racial/ethnic differences in wealth are considerably larger than those for income. For example, in 2009 in the United States, the median net worth of white families ($113 149) was more than 20 times larger than that of black families ($5677), and almost 18 times larger than that of Latino families ($6325) (Kochhar et al., 2011). Moreover, measures of wealth make an incremental contribution in predicting variations in health over and above measures of education and income (Williams and Collins, 1995).

Race, SES, and Health

Research reveals that SES differences between the races account for many of the racial/ethnic differences in health. For example, adjusting black/white disparities in health in the United States for SES substantially reduces these differences. A 2012 study (Geruso, 2012) found that income alone explained 52% of the difference between the life expectancy of black males and white males, and 59% of the difference between black females and white females. Education alone, which is closely correlated to income, explained 26% of the difference between the life expectancy of black males and white males, and 29% of the difference between black females and white females. In combination, the two factors explained 62% and 63%, respectively. Several important trends are noteworthy. For both racial groups, income is strongly linked to life expectancy. For most racial and ethnic groups, persons with lower levels of income have lower life expectancy than their more economically favored peers. In addition, the difference in health status by SES for both black and white men is larger than the overall racial difference. African-American men in the highest income group live 7.4 years longer than those in the lowest income group; the comparable number for whites is 6.6 years. The overall racial difference for men was 4.9 years. Although SES predicts variation in health for both black and white women, for women, the overall racial difference is somewhat larger than the differences between SES groups. The life expectancy data also reveal an independent effect of race, even when blacks and whites are comparable in income. At every level of income for both men

and women, African-Americans have lower levels of life expectancy than their white peers. This pattern has been observed across multiple health outcomes, and for some indicators of health, such as infant mortality, the racial gap becomes larger as SES increases.

There are exceptions; for instance, life expectancy for both Asian-Americans (87.3 years) and Latino Americans (83.5 years) is higher than that of white Americans (78.7 years; American Human Development Project, 2010/2011). While for Asian-Americans their longevity can be explained partially by their higher economic and educational status, as well as their diet and lifestyle, the longevity of Latino Americans is not so easily explained. Latinos economically have a similar profile when compared to African-Americans (74.3 years), and experience disparate medical treatment (Smedley et al., 2003), yet their group on average lives longer than even the more advantaged white group. In contrast, for whites and African-Americans, wealth predicts longevity, with the wealthier members of each group projected to live half a decade longer. Known as the 'paradox,' Latinos' SES has little bearing on their longevity. Researchers have offered several explanations for this phenomenon. In investigating the finding that Latinos have birth outcomes (i.e., low infant mortality, see **Table 3**) that are better than would be expected, some researchers propose that this has something to do with the 'healthy immigrant phenomenon,' which points out that people who immigrate are young and active and tend to be healthier than those who do not. Furthermore, newcomers are believed to have an ethic of good health habits. Another plausible explanation is that because Latino communities are composed of strong social support networks, including more extended family supports, this acts as an insulation that protects their health. However, the longer they stay within the United States and acculturate to the American lifestyle, their well-being, ambition, and health tend to deteriorate (Lamare, 2012). For instance, current rates of alcohol and substance abuse among Latinos are comparable to or surpass those of other US ethnic groups (Guerrero et al., 2013).

While the life expectancy for Asian-Americans is the highest among the four major ethnic/racial groups, the statistics are not based upon data disaggregated by ethnic subgroups and there is a scarcity of evidence-based interventions specifically adapted for and tested among Asian-American subgroups. Very little is known about disparities among the Asian-American subgroups (South Asian, Chinese, Filipino, Japanese, Korean, and Vietnamese). The lack of disaggregated data has led to overlooking the fact that the poverty rates for some Asian groups (e.g., Hmong and Cambodian Americans) approach 30%. A concomitant statistic is that some subgroups are unhealthier than others and have a much shorter life expectancy. For instance, it is estimated that Asian-Americans constitute close to 50% of the 1.4 million Americans chronically infected with hepatitis B, even though they constitute only 4% of the nation's population (CDC, 2008). Asian-Americans also have the highest race-specific rate of tuberculosis incidence (CDC, 2001) and underutilize preventive services such as colorectal, breast, and cervical cancer screenings when compared with non-Hispanic whites (Ward et al., 2004). Furthermore, many well-to-do Asian-Americans return to their native countries to receive nonurgent medical care. Thus, the present picture of Asian longevity is incomplete.

Table 3 Infant mortality rates in the United States per 1000 by race and Hispanic origin of the mother, 2005–07

Race/ethnic identity of mother	*Rate of infant mortality, 2005–07*
All races	6.8
White	5.7
Black/African-American	13.4
Hispanic/Latino	5.5
American Indian/Alaska native	8.5
Asian/Pacific Islander	4.7

Disparate Health Services and Treatment

Improved medical care and prevention efforts have contributed to dramatic increases in life expectancy in the United States, particularly over the past century. At the same time, however, the health status of some racial and ethnic minorities lags far behind that of the majority population (NCHS, 2007). This situation is especially true for African-Americans and Native Americans who both, for a variety of reasons, including poverty and overt discrimination, experience significant health disparities in comparison to white Americans. Given the cost and long-term consequences of health disparities (e.g., decreased productivity, diminished quality of life), identifying the causes can be of utmost importance. Racial disparities in care tend to remain, even after controlling for patient differences in SES, insurance status, and access to a regular primary care provider (Johnson et al., 2004).

The findings from numerous studies that ethnic minorities receive inferior medical treatment are compelling. For instance, the National Cancer Institute Black/White Cancer Survival Study examined whether cancer treatment varied for white American and African-American women. They found that African-American women received less aggressive and less appropriate treatment than white American women (Breen et al., 1999). Although white American women have a higher incidence of breast cancer, they do not have the highest mortality rate; African-American women are more likely to die from breast cancer than white American women (Lantz et al., 2006). Income and education did not account for racial differences in the stage of breast cancer diagnosis, and racial disparities in early-stage diagnosis remained significant even after controlling for income and education. Even when controlling for disease stage, the risk of death is 50% higher for African-American women with breast carcinoma than for white American women (Bradley et al., 2001). While overt racism undoubtedly contributes to this disparate outcome, a report by the Institute of Medicine (IOM) on racial disparities in health care suggests that various aspects of the physician–patient relationship may be

a major cause of health disparities in the United States (Smedley et al., 2003).

Physician–Patient Issues

Physicians diagnose disease and recommend treatment alternatives, and even when patients desire to participate in their medical decisions, they typically depend upon their physicians for guidance, options, and appropriate care. This is especially true for patients who have lower levels of education, health literacy, and SES (Lillie-Blanton et al., 1996). Furthermore, research suggests that some physicians remain unenthusiastic about treating non-white patients, particularly African-Americans (Murray, 1998). For instance, research demonstrates that African-American patients receive less positive communication, less information, fewer treatment options, and overall less instrumentally and interpersonally effective care when compared with white American patients (Cooper-Patrick et al., 1999; Smedley et al., 2003). Furthermore, less positive effect, is central to patient recall of information, treatment adherence, and satisfaction with health care process and outcomes (Johnson et al., 2004).

There is also evidence that all four groups (African-Americans, Asian-Americans, Latinos, and Native Americans), in contrast to white Americans, may have difficulties developing appropriate patient–physician relationship and trust (Vamos et al., 2009). Recent research has addressed the effects of physician–patient concordance on the process and outcomes of medical care; concordance refers to the similarity or shared identity between physician and the patient in the delivery of health care. Most concordance research has examined similarities and differences in the demographic characteristics of race, gender, and age, and this research provides some evidence that medical visits in which physician and patient are similar may be somewhat different in process and outcome than those in which physician and patient are very different. For example, race-concordant medical visits (compared to discordant visits in which patient and physician are of different races) tend to be longer, with a more participatory partnership-oriented style (DiMatteo et al., 2009). Race-concordant care also results in higher patient satisfaction, greater patient trust in and access to the physician, greater trust in the health care system, and greater respect and listening in the process of communication (Cooper-Patrick et al., 1999; Cooper et al., 2003). Also, patients in racially discordant interactions received significantly less information and were significantly less active participants when compared with patients in racially concordant interactions. Controlling for patients' participation reduced the effect of concordance on information giving, suggesting that racial discordance might increase patient passivity and reduce information exchange. It is possible that minority patients in discordant interactions do less to prompt their physicians for information, resulting in physicians offering less information to these patients.

For minorities, the importance of the negative influence of physician communication or lack of communication in health outcomes abound. For example, prostate cancer, which is the leading cancer diagnosed among men in the United States, occurs about 60% more often in African-American men than in white American men, and when it is diagnosed, the cancer is more likely to be advanced (Prostate Cancer Health Center, 2013). A study (Woods et al., 2006) that investigated prostate cancer in black men reported that the men believed that if there were a potential problem, their health care provider would communicate the seriousness; however, few providers did so. Furthermore, they reported that traditional barriers generally found in the literature regarding black men and late health care access because of a lack of health insurance, not going to physician on a regular basis, lack of transportation, and not interested in their health were *not* supported (Woods et al., 2004). They concluded that the findings were consistent with the IOM report on health care access, i.e., those blacks and other minorities receive inferior health care compared with whites across a range of health conditions and procedures, even when insurance status, income, age, and severity of condition are comparable (Woods et al., 2004).

Psychosocial Causes of Health Disparities

Although numerous studies have shown that even when health status and coexisting illnesses are accounted for, minorities are still *less* likely (1) to be referred for evaluation, (2) to receive the 'gold standard' (i.e., most effective treatment available), (3) to be rated as appropriate candidates for organ transplantation, or (4) to receive a transplant, regardless of their age and income (Vamos et al., 2009). One documented explanation is direct doctor/institutional discrimination (Smedley et al., 2003). Some researchers, however, place the burden on minority patients, who are blamed for mismanaging their health by not adhering to the medical regimens, lacking the literacy to understand the protocols, and avoiding professional medical attention. For instance, Latinos are less likely to be insured or more likely to have suboptimal insurance, which therefore limits their ability to receive many health care services. African-American men are more likely to be unemployed and thus, if they seek health care, it is more likely to be for an emergency (Disparities Report, 2003). Even Asian-Americans, who have the highest life expectancy than any of the four major ethnic groups within the United States, in contrast to whites, contend with numerous factors, which may threaten their health. Some negative factors are infrequent medical visits due to the fear of deportation, language/cultural barriers, and the lack of health insurance (OMH, 2013).

Cultural Mistrust: An Added Burden for Nondominant Populations

'Trust' in their health care provider seems to be an issue for many minorities. Cultural mistrust is a construct that was initially conceptualized to describe the distrust among African-Americans of white Americans and mainstream American institutions including the legal system, political system, government agencies, educational system, health care system, employment settings, and other entities that are governed or staffed by white Americans (Terrell and Terrell, 1981). Recently, cultural mistrust of health care providers has been investigated with other minority populations. One study found that Filipino Americans who expressed higher levels of cultural

mistrust were less likely to seek professional psychological help. Furthermore, cultural mistrust predicted variance in mental health help-seeking attitudes that are not accounted for by income, generational status, loss of face, and adherence to Asian cultural values (David, 2010).

Another study that collected data using a stratified, random-digit dial telephone questionnaire of noninstitutionalized households in New York, Maryland, and Puerto Rico, reported that compared with whites, Latinos were nearly two times more likely to report that fear of being a 'guinea pig' and lacking trust in medical people made them unwilling to participate in cancer screening (Davis et al., 2012).

Also, Native Americans, in contrast to whites, who were newly diagnosed cancer patients, expressed significantly higher levels of mistrust and lower levels of satisfaction with their health care. In multivariable analyses, race was the only factor found to be significantly predictive of higher mistrust and lower satisfaction scores. Numerous studies have reported similar findings whether it is beliefs concerning being an organ donor (Breitkopf, 2009), adherence to recommended medical regiments (Shelton et al., 2011), or receiving genetic testing (Suther and Kiros, 2009). In each case, people of color, compared to whites, were significantly more mistrusting of health care providers, and thus, more likely to avoid interacting with health providers and less likely to adhere to recommended health regimes.

A recent study investigating the connection between health and stress (Hicken et al., 2013) found that African-Americans, but not Latinos, in contrast to whites, were more vigilant. This vigilance was positively associated with sleep difficulties in all three racial groups; however, it was attenuated by income and education, and completely attenuated after adjustment for racism-related vigilance. Given the importance of sleep quality to health, anticipation of and perseveration about racial discrimination appears to be an important determinant of racial disparities in health. Interestingly, given that Latinos were less vigilant when it came to racism and discrimination, this may be one explanation of why they live longer than their African-American counterparts.

Changes in Racial Inequalities in Health

Data from the United States suggest that patterns of racial inequality change over time in response to larger socioeconomic changes. For example, the Civil Rights Movement improved the economic circumstances of blacks and narrowed the black/white gap in income during the 1960s and the early 1970s. Correspondingly, mortality rates for blacks declined, both on a percentage and an absolute basis more rapidly than those of whites between 1968 and 1978 (Williams and Collins, 1995). Similarly, during this time period, the life expectancy increases for black males and females were larger on both a relative and an absolute basis than those for whites. However, the economic status of blacks relative to whites stagnated in the mid-1970s and worsened during the 1980s. Similarly, the black/white gap in multiple health indicators worsened during this decade. The black/white gap in life expectancy, infant mortality, and excess deaths increased between 1980 and 1991 (Williams and Collins, 1995). For example, for five consecutive years after 1984, the life expectancy at birth for blacks progressively declined, while that of whites continued to increase progressively.

The economic downturn following 2008 has also been associated with worse health outcomes in the United States, especially among economically disadvantaged minority groups. African-American, Hispanic, and Asian children have been reported as having a higher incidence of asthma in the years immediately following the 2008 downturn (Burgard, 2012). All groups reported increased psychological distress. These data are consistent with research, which shows that the health of populations is affected by a broad range of economic factors, including growth, stability, and inequality (Brenner, 1995). For example, mortality from all causes tends to increase about 2 to 3 years after the low point of a recession. These data highlight that both race and SES have powerful influences on health because they shape the experience of and exposure to almost all psychosocial and environmental risk factors for health.

Resources and Acculturation

Health-enhancing resources exist even in the most disadvantaged racial and ethnic populations. Much research on the health of disadvantaged groups has focused historically on pathology and vulnerability. However, the available health data clearly suggest that health-enhancing factors also exist within contexts of economic deprivation. For example, despite high rates of poverty and low rates of health insurance coverage, Mexican immigrants still have a relatively good health profile, with relatively low rates of infant mortality and longer life expectancy than many other groups. Similarly, although black Americans have lower levels of income and lower life expectancy, their rates of suicide are markedly lower than whites, and blacks tend to have equivalent or lower rates of psychiatric illness compared to whites. These data suggest the need to identify cultural strengths and health-enhancing resources that exist within disadvantaged communities; this may shield these populations from at least some of the negative exposures in their social context. For instance, research has found that quality of family and extended kin relationships, as well as religious participation are key health-enhancing resources that help to reduce some of the negative effects of stress on the health of disadvantaged populations. More research is needed on the mechanisms and processes by which these factors operate, and the ways in which they combine with existing risk factors to affect health.

In many societies, minority racial and ethnic groups are largely immigrant populations. The health profiles of these groups may reflect their immigrant status, and may change with increasing length of stay in the host society. In the United States, immigrants of all the major racial/ethnic groups have lower rates of infant and adult mortality than their native-born counterparts (Green, 2012; Williams, 1999). Importantly, these patterns persist even when immigrant groups, such as Mexicans in the United States, are lower in SES and have limited access to medical care. At the same time, other data suggest that, across a broad range of health status indicators such as infant mortality, low birth rate, cancer, high blood pressure, adolescent pregnancy, and psychiatric disorders, the health status of

immigrants worsens with length of stay in the United States (Williams and Collins, 1995). The mechanisms and processes responsible for these negative effects of acculturation are not fully understood. Several behaviors that adversely affect health status appear to increase with length of stay. It has also been suggested that there may be health-protective aspects of indigenous cultures and belief systems that are lost with increasing time in a new society.

Culture is a construct that is widely invoked in discussions of racial and ethnic variations in health. However, it is often treated as a residual explanation for unexplained differences in health. There is a critical need for the theoretical identification and the empirical assessment of the specific cultural beliefs and behaviors that are presumed to affect health. Moreover, researchers must avoid labeling as cultural what are more structural differences in the social position of different groups. Culture is dynamic and its development and persistence must be understood within the context of powerful reciprocal influences that are operative as social groups interact with the constraints and opportunities of their specific environment.

Concluding Recommendations

Future research on racial/ethnic variations in health should include an assessment of the considerable ethnic heterogeneity that exists within all the widely used racial categories. Researchers in this area must recognize that there is no generic health model that applies equally to all racial or ethnic minority populations, but that particular indicators of disease prevalence or health can be used comparatively if data has been carefully and consistently collected. Research and health policy regarding race/ethnicity should be attentive to the distinctiveness of each group, including using the terms that are broadly recognized and preferred by a substantial proportion of respondents of the groups being studied. The fluidity of racial and ethnic categories requires periodic monitoring and updating measures of racial and ethnic status. Importantly, whenever racial and ethnic data are reported, more attention must be given to the interpretation of these data. For example, it is always necessary to indicate why race or ethnicity is being utilized, the limitations of racial and ethnic data, and how the findings should be interpreted. Given the strong association between racial/ethnic status and SES, the presentation of data on racial differences should routinely stratify them for SES within racial groups. Failure to attend to these issues of presentation and interpretation may oversimplify complex health risks and even perpetuate negative racial stereotypes. Finally, future research must conceptualize and operationalize the specific factors and practices linked to race that might affect health.

Race: Ethnicity and Urban Planning

June M Thomas, University of Michigan, Ann Arbor, MI, USA

Abstract

This article discusses how urban planning has affected different racial and ethnic groups, and in turn how race and ethnicity affect the work of urban planning. The article summarizes some of the concerns with previous planning efforts in minority communities, but it argues that social justice is important for both individuals and institutions and remains an important consideration for urban planning as a field. Short discussions of the subfields of land use regulation and of housing, only two of many possible urban planning specializations, offer examples of the interaction of race, ethnicity, and urban planning.

This article discusses those aspects of urban planning that affect or are affected by varying conditions facing different racial or ethnic groups. 'Urban planning' – also known as urban and regional planning, or as town and country planning, depending on the country of practice – concerns the location, arrangement, and quality of housing, transportation, environmental protection, community services, land use, or commercial facilities. These activities can have many positive effects on residents of a city or region, but in certain contexts they may also exacerbate social inequality.

The word 'race' typically refers to one of several broad categories of humanity, such as Caucasian or 'white,' Asian, or dark African heritage or 'black,' but such categories are not well-defined biologically. Furthermore, different countries define race differently; some countries treat immigrants from the same nation or region as one race, but these groups may have marked internal differences. In some parts of the world, ethnic or religious differences are much more significant than racial differences (Yiftachel, 2006). Therefore, both race and ethnicity are referred to while discussing planning. The term 'ethnic' is used to mean groupings of people bound by historic ties such as language, nationality, or customs, a definition that will vary depending on context. The focus here is on how inequality by race or ethnicity relates to urban planning in a particular place of practice, such as a metropolitan area or a nation.

Background of the Issue

The linkage between urban planning and race arose in modern multiracial societies because decision makers sometimes used urban planning tools as strategies for racial oppression or exclusion of relatively powerless racial or ethnic groups. In the United States, during the early part of the twentieth century, some of the first tools that professional urban planners used to regulate land use enforced the residential segregation of African-American households from white households (Silver, 1997). In societies characterized by white colonialists living in subject territories, European powers used urban planning tools to make sure that the spatial arrangement of urban settlements mirrored official roles. Grand approaches to colonial government buildings sent a visual message that the European colonial governments and their citizens were dominant. Residential areas for Europeans had much higher standards of services and housing than sections set aside for 'natives.' Planning was therefore used as an expression of power and subjugation in the guise of order and sanitation (Boyer, 1983; Hall, 1996; Njoh, 2009).

As multiracial urban societies evolved during the twentieth century, many governments abandoned the purposeful isolation of supposedly subordinate racial groups but developed other mechanisms of oppression. Some US localities used urban redevelopment programs to isolate racial or ethnic minorities, either through building racially segregated public housing or clearing minority-race or minority-ethnic neighborhoods with the help of federal 'urban renewal' funds. The rationale was often the low quality of targeted-area housing stock, due to residential secession and poverty, and many planners in fact saw themselves as serving both the public interest and the poor by carrying out such policies (Thomas, 1997). Yet local planners did not always recognize the right of targeted-area residents to live in low-income but viable neighborhoods or to participate in decision making about clearance of their own communities, and federal policy did not offer adequate financial support for relocation to other areas. Furthermore, such redevelopment took place during an era of racial segregation in housing, leading to few options for ousted residents who were black. Federal 'urban renewal' thus led to spirited protests in the 1950s and 1960s (Wilson, 1966). The outcry over this program, nicknamed 'Negro removal' because so many targeted neighborhoods were black, led to significant reforms in US federal policies and local planning activities, including the rise of a movement of planners devoted to the cause of social justice (Thomas, 2012). Yet racial segregation was so entrenched in other ways that it proved difficult to lessen simply by changing federal and local policies.

In other parts of the world, as colonialism withered, indigenous residents of former colonies arose to plan their own cities but nonetheless faced significant social divisions because of caste, class, or ethnicity. It was not atypical for native-race government workers to move into the same districts once inhabited by white colonial settlers, and to enjoy better benefits in municipal services and housing than poor or working-class residents. In some locales, certain ethnic groups gained higher status over others, again mirrored in living conditions. Although planners often worked to improve living conditions for the less privileged, they also sometimes protected urban structures reflecting the fissures of socioeconomic status.

Although the purposeful use of urban planning tools to enforce racial subordination, isolation, and segregation waned by the early twenty-first century, the problem has not gone

away. Subtle exclusion still characterizes seemingly innocuous urban planning decisions. Yet the nature of the issues has changed markedly as broader societal questions have changed. In urban South Africa, for example, the end of apartheid has ended legally enforced spatial segregation by race, but not uneven settlement or development (Beauregard, 1998; Watson, 1998). In modern Europe, immigrants of color have sometimes taken on the role of 'other' and faced prejudices and exclusions. In the United States, decision makers use planning tools to help maintain autonomy and exclusion by income status if not by race or ethnicity. Thus, the conversations continue even though the particulars may differ.

Areas of Scholarly Inquiry

Bauman has suggested four main categories of scholarships related to race in planning history (Bauman, 2002). Bauman's first category includes scholars who see minority groups as victims of planning decisions. A second category views race, ethnicity, or class as issues necessary to understand the inherent 'structure or contours' of urban society. The third category would treat minority groups as purposeful agents involved in shaping the urban environment. A final category would view such groups as simply part of a larger picture composed of various actors. The author focuses here on Bauman's first, second, and third categories, victimization, impact on urban structure, and activism.

Another way to look at scholarship in this area, other than Bauman's continuum for planning history, would be to consider contemporary planning-related specialty areas such as planning theory, land use, housing, transportation, environment, urban design, economic development, or others, examining each topic for racial or ethnic implications. To do this, however, would be a daunting and lengthy task for this summative narrative. Instead, the next section will briefly discuss social justice in planning theory as well as additional implications of Bauman's continuum; these ideas would apply to any planning specialization. Then a following section will briefly summarize specific concerns in two of the many possible specialty areas in planning: land use and housing.

Social Justice, Urban Structure, and Agency

Historically, urban planning tools and programs have sometimes oppressed racial or ethnic minorities, as in Bauman's first category, victimization. Much of this literature is based in the United States (Thomas and Ritzdorf, 1997; Sandercock, 1998; Gillette, 2006). Such scholarship once focused on planning inequity between blacks and whites, but recently, scholars have offered more careful study of groups such as Hispanics and indigenous peoples (Irazabal and Farhat, 2008). Contemporary planning literature also examines circumstances around the globe, particularly in Europe and the Middle East (Thomas, 2000; Bollens, 2006; Maginn, 2004). Such scholarship has often shown that planning actions do not always protect social justice for subject, oppressed, or disadvantaged populations.

Justice and social justice are complicated topics, but some authors have helped to link these ideas to urban planning. Notable among these are David Harvey, whose book *Social Justice in the City* was foundational (Harvey, 1973), and Iris Marion Young, who helped define justice in the context of distinctly identifiable groups. Young warned against judging people solely by their group membership, as individuals can differ, act on free will, or belong to several overlapping groups; yet, at the same time, she noted, certain definable social groups deserve the ability to give voice to their protests against oppressive treatment. Suggesting that clustering was not always bad, she stressed that certain groups should be able to cultivate their own identity without exclusion or forced immobility (Young, 2000; Fainstein, 2007). Furthermore, she noted that social and political systems need to correct social wrongs even though individuals also have justice-related obligations. Other urban scholars who wrote about social justice often referenced her work (Harvey, 2002; Fainstein, 2000, 2010; Soja, 2010). They echoed the need for planning-related decisions to avoid oppression of various kinds, involve all affected parties in decision making, and offer equitable access to resources.

The responsibility for social justice lies largely with social and political systems, Young argued, but individuals still have responsibilities to help right social wrongs. Urban planners may not always be in a position to counteract such social wrongs easily; they may work as civil servants or consultants, and they may answer to elected or appointed officials as their employers; these employers could very well push for objectionable decisions. Yet planners have advisory power and implement some programs, and they need to have a sense of planning professionalism that eschews social oppression and promotes social justice.

Thus, codes of professional ethics enter this discussion. One way to deal with the historical and contemporary dilemmas caused by a racially fragmented society is to create a professional code of ethics that specifically exhorts support for social justice. Both general principles of ethical behavior promoted by the American Planning Association and the professional code of ethics enjoined by the American Institute of Certified Planners (both in the United States) encourage planners to support opportunities for those who have few, to give voice in planning decisions to those who may be marginalized, and to recruit diverse peoples into the planning profession. Certified planners in the United States, furthermore, should explicitly promote racial integration, according to their code. In South Africa, the code is weaker on this dimension: planners need only promote equality and avoid personal discrimination, while the UK code prohibits discrimination of several types (see Web pages at end of article). Although these official ethical provisions can be quite limited, they do offer at least some support for nondiscrimination.

Bauman suggested a second category of study: the effects of race on urban form and structure. Urban studies in the United States analyze residential segregation as a way of studying race and ethnicity in the context in which planners must work. The topic of segregation has also become increasingly important in many other countries experiencing the clustering of various ethnic groups and nationalities, since such urban patterns affect access to jobs, housing, high-quality schools, and other public services. Journals such as *Urban Studies* have published studies from around the world about similar issues. More connected with the disciplinary areas of the social sciences than with urban planning, these works are nevertheless important to

urban planners. Documentation of segregation by race, ethnicity, and socioeconomic status helps explain the nature of urban form as well as identify possible circumstances needing action. Other works focus not so much on residential segregation as on changes in urban structure, urban policies, or development plans that race or ethnic divisions affect, such as US literature on post-Hurricane Katrina New Orleans (Lowe and Shaw, 2009), on economic opportunity fettered by racial exclusion (Harper-Anderson, 2008), or on metropolitan divisions by race that affect the ability of a region to prosper (Jacobs, 2009).

Activism by minority-races or ethnicities themselves, the third of Bauman's suggested categories, is also an important area of study. One way to frame this activism is simply as community development, which means the organized efforts of groups to develop and support their own communities. Soja (2010) describes such activism in Los Angeles, but a number of other books and articles do as well, and the concept of community development itself is by no means limited to groups defined by race or ethnicity. One line of studies has shown that activism in matters related to land use is a particularly fertile area for indigenous peoples or ethnic groups in multiracial societies (Jojola, 1998; Lane and Hibbard, 2005), including a growing-related literature concerning North American Latinos (Morales, 2010; Carpio et al., 2011). The environmental justice movement also highly values activism carried out by oppressed minorities confronted with disproportionate exposure to poor or toxic environmental conditions (Bullard, 1993; Agyeman, 2005). At this point, however, much more literature exists on the victimization aspect of the relationship between race/ethnicity and planning than on racial or ethnic minorities as activists.

Land Use and Housing

Land use and housing are generally two different planning specialties but they are closely related when discussing race and ethnicity. Zoning refers to one specific aspect of municipalities' legal regulation of land use or buildings and is a commonly used planning tool. Land use decision making may routinely exclude people as possible residents on the basis of socioeconomic status, ethnicity, or race. An example would be zoning ordinances that exclude low-income or multifamily housing, or housing on relatively small lots. The general term for such discriminatory action is 'exclusionary zoning.' In the early twentieth century, some locales set up zoning categories based on racial exclusion, but these are now in most parts of the world illegal; South Africa, under apartheid, was one of the last holdouts. Yet in metropolitan areas in which low-income racial minorities are isolated and segregated in some municipalities, zoning that permits only (or mostly) low-density single-family housing may have much the same effect as would zoning exclusions based on racial characteristics (Massey and Rothwell, 2009; Dyble, 2010; Rothwell, 2011).

In the United States, although overt racial discrimination in housing rental or purchase violates civil rights laws that date back to the 1960s, the federal judicial system will not substantially challenge socioeconomic exclusion through zoning rules, which localities use to regulate or limit various types of residential housing. Yet local residents in privileged or middle-class municipalities commonly oppose subsidized, low-income, or multifamily housing, a situation that may have enormous racial or ethnic implications. The failure to allow low-income plaintiffs who seek affordable housing in suburban communities to gain 'standing' has effectively shut off an important route to access to suburban housing for many inner-city minorities (Federal Courts – Standing, 2007). Although 2010 census figures showed that minority-race suburbanization is increasing, this integration has spread unevenly across metropolitan space; blacks, for example, are moving to some suburbs but not others, and they remain far more isolated than any other minority groups.

Planners in diverse societies are reshaping land use regulations to recognize special needs of ethnic minorities. For example, in Canada many regulations for buildings and land use concerning religious facilities assume that any religious building would be a free-standing church. An immigrant-rich context in which Muslims of different Middle Eastern nationalities are increasing in numbers has required creative flexibility in many ways. A common sequence for such immigrants is to begin to meet congregational needs by holding smaller then larger meetings in residential houses, a situation that might counter traditional zoning regulations. When growth in size or finances allow, these groups may then move to rented stores or other buildings, and then construct mosques with unique architectural or sound-system features not allowed by regulations designed only for Christian churches (Qadeer, 1997). Similar issues have arisen in Great Britain and other countries (Gale, 2008).

Aside from the issue of exclusion of certain kinds of residential land use, the problem of making sure that members of various minority groups have adequate housing faces planners in many different countries. In developing countries, the problem may very well be a lack of societal resources to make sure that the population is well housed, although even there it is not difficult to imagine different access to housing resources based on differing ethnic status or race. In more developed countries, the problem of unequal access to housing is connected with the issue of urban structure; certain areas of cities or metropolitan areas are very likely to have better housing resources than other areas, and when conditions of inequality exist, housing resources likewise differ.

In such situations, the social responsibility of the urban planner who focuses on housing would be threefold. First, as mentioned above, where certified planners have a clearly stated professional obligation to help promote integration, as in the United States, seeking ways to promote this should be the planner's goal. A few experiments in residential integration for racial minorities have led to suburban resistance, such as with the United States' Moving to Opportunity program (Briggs et al., 2010), but other opportunities exist to make less drastic changes in racial patterns. Second, in those places with antidiscrimination laws, the planner would be obligated to follow those laws and to discourage efforts to block racial or ethnic minorities from available housing. But the third strategy is perhaps the most common for housing planners. That is to work within existing programs to find the financial and political resources needed either to protect or upgrade existing housing or to build new residential units. Training for planners interested in promoting housing would include full exposure to

various private and public financing programs for housing rehabilitation or construction. The planner would then need to make sure that such resources were made available with no exclusion based on race and ethnicity and perhaps with special targeting to minority populations.

In some places, governments have been involved in building low-income housing for some time; depending on the country and program, the label for such housing could be public housing, estate housing, social housing, or subsidized housing. Although strategies to purposefully isolate racial or ethnic populations in such low-income housing are increasingly rare in the 2000s, the practical result of building such housing in self-contained complexes may indeed be social isolation. One possible task for planners would be to strive for income or racial diversity in such housing, or to work with ethnic and racial groups to assure that the government-subsidized housing meets their needs. In only a few places, such as Singapore, has the government actually set up quotas for various ethnic groups in different public housing developments (Sin, 2002), a common practice in the United States in the 1940s. In Singapore, the goal apparently is to promote balance rather than exclusion.

Responses to Inequality and Injustice

Urban planners have reacted in several ways to the continued problems related to the connections between racial injustice and urban planning in diverse societies. Scott Bollens has offered a typology of responses that is useful as a framework for discussion (Bollens, 1988).

One category that has already been discussed includes those planners who try to reduce inequalities between groups. Many urban planners in the United States, for example, consider the advocacy planning and equity planning movements to have laid the groundwork for important responses to the racial crisis in their country, and progressive planning has continued as a label for those concerned about such ends. The concept of equity planning is a practical response to the crises of local policy caused by racial segregation and poverty in American cities. This particular approach suggests that urban planners can and do rise above the limitations of government bureaucracy and pursue other local policies to channel direct benefits to people hindered by race, ethnicity, or socioeconomic status (Krumholz and Forester, 1990). Several key planners and scholars have explicitly addressed the important role of race in helping to create the unjust conditions to which planners must respond, and their concepts have influenced the US professional code of ethics. Specific groups of planners have worked to directly address the needs of various racial and ethnic minorities and the poor through their work and to raise attention to their cause in several venues, including the planners' professional and academic organizations. (See Web page links below.)

A second possible response by an urban planner is to side with the status quo in the name of objectivity, even in the face of blatant inequities. The urban planner or policy is supposedly 'neutral,' but in fact may reinforce the position of the dominant group. Such a so-called neutral planner may refuse to acknowledge or address issues of segregation or polarization. The shield, under such circumstances, is that urban planning – or at least their version of it – is a professional exercise not heavily involved with issues of social inequality. This particular attitude may actually be hurtful when exemplified by planners in circumstances of major inequality or racial or ethnic conflict. The claim that the planner is 'color blind' may be only a poor excuse for collaboration with systematic injustice.

A third response might be called 'partisan,' where the planner rejects the concerns of powerless groups and sides with the powerful. The city's government and civic leaders view neighborhoods and policies through a lens colored by race or ethnicity, and the interests of the dominant group sets the norm for professional urban planners. As the political leaders set the policies, the urban planners carry them out, even in the face of blatant favoritism or discrimination. Bollens offered several examples from South Africa, but also noted the same syndrome in Jerusalem, where the systematic and purposeful isolation of Arab neighborhoods had gained the force of righteousness. Similar trends existed in Belfast, Ireland, where religion was the primary divider. As Bollens noted, somehow local urban planners were able to function without any noticeable discomfort about the obvious partisanship of their actions.

Finally, Bollens referred to 'a resolver strategy,' which attempted to address the root causes of power imbalances, competition among racial and ethnic groups, and disempowerment. This approach then aimed to confront the status quo call and profoundly transform the system. Although this approach is in some ways simply a more impassioned form of equity planning, it also has broader implications in countries such as South Africa. There, for example, resolvers have begun to carry out development planning that differs markedly from traditional urban planning activities, which favored white areas and white concepts. Development planning, in contrast, more fully integrates spatial planning with social and economic planning. It restructures policy directions by cutting across traditional departments and governments, and it uses a participatory process to help empower marginalized people. It would involve more members of the victim class as professional planners than was previously the case.

It is this last point, the need to involve the subordinate social group in professional planning, that has led to much discussion about the challenge of diversifying the urban planning profession as well as the planning academy. Although strides have been made in doing so, diversity is still lacking both in the profession and in planning education, and a number of challenges remain in terms of rectifying this shortcoming (Wubneh, 2011; Sweet and Etienne, 2011).

That the urban planning profession maintains an ongoing dialog about issues related to resolving social injustice is a healthy sign. Although many societies remain severely fragmented and alienated by race, the situation is open to proactive effort to improve existing conditions. As larger societies become more comfortable with multiculturalism and multiracialism, urban planning as a field can and will adjust.

Race: Genetic Aspects

Guido Barbujani, University of Ferrara, Ferrara, Italy

Abstract

Genetic research has shown that all individuals and populations are different, but no agreement has ever been reached on the number and definition of human races, with proposed races numbering from none to 200. Human genetic differences are patterned in geographical space, but each population harbors a large proportion of the species' diversity and shares with other populations most of its genetic variants. Race remains an important component of our social and psychological world, but envisaging humans as subdivided in genetically differentiated races leads to poor evolutionary inference and to errors in clinical practice.

Introducing geographic variation in his classical book *Systematics and the Origin of Species*, Ernst Mayr (1947) makes a distinction between species in which biological changes from population to population are continuous, and species in which populations with different character combinations are separated by borders. In the latter, the entities separated by borders are called subspecies or geographic races. Similarly, in human genetics (see, e.g., Vogel and Motulsky, 1986) and anthropological (Brues, 1977; Molnar, 1998) textbooks, races are often envisaged as large populations of individuals who have a significant fraction of their genes in common and can be distinguished from other races by their common gene pool. Under both definitions, increased levels of genetic similarity among members of a race is the result of shared ancestry.

The idea that races are a natural feature of human diversity has long set the standards for anthropological research. For centuries, people sharing the same 'blood,' especially in noble families, were said to form a race (Furetiere, 1690, cited in Cohen, 1991). In the eighteenth and nineteenth centuries, the word acquired a more general meaning, coming to designate constant human types, and it was used both to describe and to explain human diversity. Scientists investigating human variation classified people in different races and explained their differences as a consequence of their belonging to different races. That view is based on an empirical observation and on an assumption. The observation is that members of the same community look similar, whereas people from abroad look different; the assumption is that these similarities and differences reflect our species' natural subdivision in clusters of individuals sharing common ancestors. Testing that assumption at the genetic level became possible only in the second half of the twentieth century.

In the meantime, however, the race concept has become intrinsically ambiguous. For creationists, including Linnaeus, species were fixed entities, and so there was no conceptual difficulty in assigning individuals not only to species, but also to subdivisions of lower taxonomical rank. However, Lamarck's and Darwin's proposal that different species arise with modification from common ancestors implies that borders between them are fluid and evolve with time. As a consequence, species are now regarded as groups of organisms capable of interbreeding and producing fertile offspring, reproductively isolated from other such groups (de Queiroz, 2005). Accordingly, a race or subspecies is a genetically differentiated group of organisms on its way to developing reproductive isolation from other groups of the same species, but not there yet; this way, its borders are, by definition, uncertain.

In practice, some subspecies may be rather obvious. In several plant and animal species (e.g., the Hawaiian amber snail; Holland and Cowie, 2007), the greatest fraction of the overall genetic diversity occurs between populations or groups of populations. When that is the case, most individuals of unknown origin can be assigned with a good degree of statistical confidence to one group on the basis of their morphological or genetic characteristics, and these groups are likely to have a common ancestry. However, in other organisms genetic differences between populations are small and each population harbors extensive variation (one example is the Bluefin tuna, Riccioni et al., 2010).

Tuna are highly mobile animals, snails are not, and in general sharp genetic differences between populations are observed in species in which isolation prevails over migration. One question, then, is whether the patterns of human genetic diversity have been shaped by factors isolating or connecting populations, with isolating factors promoting the establishment of a racial structure. Two related questions are whether genetic differences between humans are large enough for a racial classification to be (1) possible and (2) useful for purposes such as understanding human differences, reconstructing past demography, diagnosing disease, or providing effective medical treatment.

Listing Human Races

Science has left creationism behind, but the idea that a scientific study of humans starts from their racial classification was long unchallenged (Cohen, 1991) and still remains attractive to some. People differ in many aspects; we all recognize variations in facial traits, height, body structure, skin, and hair color; although social status affects the way people are classified in races (Weeks and Lupfer, 2004), often this variation allows one to guess with some accuracy a person's geographical origin. The classical, or typological, approach consists then in identifying some basic human types, defined on the basis of such traits, and then attributing each individual to one of those types, or

races. Ideally, most individuals and populations should fall unambiguously into the appropriate group, except perhaps for a minority of them, which would be regarded as derived from interracial crosses. However, even in the early years it was evident that single morphological traits do not allow a stable classification. As a consequence, races were generally defined by combinations of traits, occasionally including cultural variables such as language, house-building and tool-making techniques, and mating systems (Cohen, 1991).

An incomplete selection of the many racial catalogs proposed using a typological approach is in Table 1; for a broader treatment of this issue, see Cohen (1991) and Molnar (1998). The first scientific attempt can be traced back to Linnaeus' nineth edition of *Systema naturae*, in which six races were proposed. Two of them consisted of individuals with congenital pathologies (*Homo sapiens monstruosus*), and hybrids between humans and other species whose existence has not been confirmed by subsequent studies (*H. sapiens ferus*). Each of the other four races (*europaeus*, *luridus*, *afer*, *americanus*) corresponded to one element of classical Greek philosophy (air, water, earth, fire) and was defined by both physical and psychological traits. Some of the most prominent naturalists of the nineteenth century, Buffon, Blumenbach, and Cuvier among them, modified Linnaeus's taxonomy, splitting or collapsing some of the previously proposed races.

Table 1 Some lists of proposed human races

Author	*No. of races*	*Races proposed*
Linnaeus (1735)	6	Europaeus, Luridus, Afer, Americanus, Ferus, Monstruosus
Buffon (1749)	6	Laplander, Tartar, South Asian, European, Ethiopian, American
Blumenbach (1795)	5	Caucasian, Mongolian, Ethiopian, American, Malay
Cuvier (1828)	3	Caucasoid, Negroid, Mongoloid
Deniker (1900)	29	
Weinert (1935)	17	
Von Eickstedt (1937)	38	
Coon et al. (1950)	30

Compiled from Madrigal, L., Barbujani, G. 2006. Partitioning of genetic variation in human populations and the concept of race. In: Crawford, M H., (Ed.) Anthropological Genetics. Theory, Methods and Applications. Cambridge University Press, Cambridge, pp. 19–37; Coon, C S., Garn, S M., Birdsell, J B., 1950. Races. C. Thomas, Springfield, Illinois; and Garn, S M., 1961. Human Races. C. Thomas, Springfield, Illinois, where the original bibliographical references can be found.

In Table 1, a problem and a trend are evident. The problem is that it is fairly simple to list some typical features of a population, but each human group, however defined, includes people who do not much resemble the typical individual. This leads to a number of ambiguities, reflecting the classifier's standpoint; for example, the number of possible skin colors recognized by different scientists has fluctuated between 4 and 34 (Cohen, 1991). The trend is partly a consequence of the problem. When the European and North American experts came in contact with new populations, it generally proved difficult to fit them into the existing lists of races, which were repeatedly expanded, reaching figures around 200 in the twentieth century (Molnar, 1998). However, increasing the number of races created additional problems because their borders became more and more elusive. As a result, contradictions emerged between catalogs proposed by different authors, and even by the same author (see Risch et al., 2002 for an example). Things were by no means clearer when it came to practical applications of the race concept. Since 1890, the U.S. Census Bureau has been asking residents to choose the race with which they most closely identify; the number of possible answers changed almost every decade, from 8 (1890) to 11 (1920), 9 (1930), 12 (1960), 6 (2000), and 15 (2010).

In time, this led to a critical reconsideration of the validity of the race concept for humans. In an article entitled "On the Nonexistence of Human Races," Frank Livingstone (1962) observed that different genetic loci give discordant information on the individuals' relationships, that human genetic variation is distributed in continuous gradients over the geographical space, and that boundaries between groups are anything but obvious. Other scientists disagreed; Theodosius Dobzhansky (1973) maintained that human biological diversity is properly described in terms of racial differences; he also admitted that no consensus had yet been reached on the number and definition of human races, but predicted that future genetic studies would settle the issue. The debate is still open. More recently, inconsistencies in racial classification were recognized, but not taken to invalidate the race concept, by authors such as Levin (2002) and Harpending (2007). By contrast, Brown and Armelagos (2001) and Relethford (2003) asserted that a classification system based on ill-defined categories has no scientific value. Dealing with the philosophical aspects of this question would be out of place here, but to test genetically the validity of the race concept, some degree of agreement is needed on the number and definition of human races.

Apportioning Human Diversity

The future that Dobzhansky was looking forward to has come; it is now possible to quantify levels of polymorphisms, that is, levels of genetic diversity, between individuals and

populations. To put these data in a more general context, one has to remember that the (haploid) human genome size is about 3.2 thousand million nucleotides; that some 36 million variable nucleotide sites are known (see http://browser.1000genomes.org/index.html); that the average nucleotide difference between humans and chimps is about 40/1000 (Varki and Altheide, 2005), and between random members of our species 1/1000. The percentages of the global species variance reported below are fractions of the last-mentioned figure.

Various statistical methods are used to apportion diversity within and between human groups, but the conceptual framework is rather constant. Groups are defined on the basis of independent evidence. Each individual is compared to all other individuals studied, and their genetic differences are counted. Three statistics are then estimated from those counts, namely, the average genetic variance: (1) between individuals of the same population; (2) between populations of the same group; and (3) between groups (Table 2). This approach of breaking down the overall genetic diversity in three hierarchical components was pioneered by Lewontin (1972), who in the pre-DNA era analyzed protein variation at 17 genetic loci. In that and successive studies, seven-race (Lewontin, 1972; Latter, 1980) or three-race classification systems (Ryman et al., 1983) were tested; in all cases, individual differences between members of the same population accounted for some 85% of the global human variance (Table 2), with values for individual loci ranging from 63.6 to 99.7%. Belonging to different populations added between 3 and 8% to that value, and belonging to different groups or races between 6 and 11%. At the protein level, therefore, variation among putative races seems to represent less than one-tenth of our species' overall genetic diversity.

At first, these proportions appeared counterintuitive, but later DNA analyses confirmed them with remarkable precision (Table 2). In practice, each human population seems to harbor a large share of the genetic diversity of the whole species. If we arbitrarily set to 100, the maximum genetic difference between two humans, the expected difference between members of the same community (excluding close relatives) is about 85, that is, much more than previously illustrated definitions of race appear to imply. This 85% figure was estimated from isolated populations of anthropological interests, rather than from urban populations, which would be a more typical sample of humanity. A UN document released in 2008 reports that, in fact, half of all humans live in urban areas. This means that the within-population component of variance is substantially underestimated in the available genetic studies and that, if subjects were sampled totally at random over the planet, differences between populations and groups thereof would account for an even smaller fraction of the species' variance.

The Genome Revolution

An impressive amount of data on human genomes, including at present nearly 1000 complete genome sequences, has accumulated in the last decade (see Clarke et al., 2012). Analysis of genomic data is showing why it has proved impossible so far to find an agreement on the main genetic groups of humankind. Xing et al. (2010) analyzed nearly 250 000 Single-Nucleotide Polymorphisms (SNPs), at none of which a fixed difference would distinguish any pair of continental populations. More than 80% of human SNPs are cosmopolitan: That is, the two alleles occur, at different frequencies, in all continents (Jakobsson et al., 2008). Combinations of alleles on the same chromosome, or haplotypes, have a clearer geographical distribution, but, with the only exception of Africa, continent-specific haplotypes are but a small proportion of the total haplotypes of the species (Jakobsson et al., 2008). A similar pattern was found in the analysis of long DNA stretches, or haplotype blocks, in which two main classes of haplotypes were described, one exclusively African, including 26% of the blocks, and the other worldwide distributed, including more than half of the blocks (Gabriel et al., 2002). We can summarize these findings by saying that, with limited exceptions,

Table 2 Estimated fractions of the global human diversity at three hierarchical levels of population subdivision

Polymorphism, number of loci	*Reference*	*Within population*	*Between populations, within race or continent*	*Between races or continents*
Protein, 17	Lewontin (1972)	85.4	8.3	6.3
Protein, 18	Latter (1980)	85.5	5.5	9.0
Protein, 25	Ryman et al. (1983)	86.0	2.8	11.2
Autosomal DNA, 109	Barbujani et al. (1997)	84.4	4.7	10.8
Autosomal DNA, 90	Jorde et al. (2000)	84.8	1.6	13.6
Autosomal DNA, 21	Romualdi et al. (2002)	82.9	8.2	8.9
Autosomal DNA, 377	Rosenberg et al. (2002)[b]	93.2	2.5	4.3
Autosomal DNA, 377	Rosenberg et al. (2002)[c]	94.1	2.4	3.6
Alu insertions, 100	Watkins et al. (2003)	88.6	1.9	9.6
X chromosome, 17	Ramachandran et al. (2004)	90.4	4.6	4.9
Autosomal Insertion/deletions, 40	Bastos-Rodrigues et al. (2006)	85.7	2.3	12.1
Median, all loci		85.5	2.8	9.0
Median, normalized[a]		87.9	2.9	9.2

[a]These values were obtained by considering all studies equally informative. The medians of their results at the three levels of population subdivision were normalized by dividing them by the total (97.3) and multiplying by 100.
[b]Considering five groups: Africa, Eurasia, East Asia, Oceania, and Americas.
[c]Considering the seven groups obtained by further subdividing Eurasia into Europe, Middle East, Central/South Asia.

variable regions in human DNA belong to two main types: either specifically African or generically human. In addition, and in agreement with Livingstone's (1962) intuition, different sets of polymorphisms, and especially Copy Number Variants (CNVs) versus SNPs, show different geographic distributions (Redon et al., 2006), and hence would suggest contradictory subdivisions of individuals and populations (Jakobsson et al., 2008).

In most genomic studies, the global variance is estimated at two levels only, namely, between members of the same population and between populations. The latter component, essentially the sum of the last two columns of Table 2, is summarized by Wright's F_{ST}-statistic. Studies differ in terms of the number of populations and individuals considered, the number of polymorphisms and the class of polymorphisms, whether SNPs or CNVs (Table 3). In principle, values of F_{ST} range from 0 (indicating that all populations are identical) to 1 (indicating maximum genetic differences between populations). When estimated from human genomic data, they are generally close to the normalized median of Table 3, that is, around 0.12 or 0.13, with a minimum of 0.05 (Auton et al., 2009). This confirms that they account for roughly 13% of the species' genetic variance, with the remaining 87% representing, on average, the difference between individuals of the same population. Once again, different loci vary greatly in their F_{ST}s, even when they map on the same chromosome (Coop et al., 2009).

Analysis of interpopulation differences shows that both allele frequencies and DNA sequences vary nonrandomly in space, often forming gradients over entire continents (Ramachandran et al., 2005; Liu et al., 2006). We also know that zones of sharp genetic change, or genetic boundaries, exist and tend to overlap with various kinds of migrational barriers, both physical (e.g., mountain ranges or large bodies of water) and cultural (especially language boundaries) (Sokal et al., 1990). However, very seldom do genetic boundaries form complete rings around single populations or groups of populations. Virtually all populations studied are somewhat different from their neighbors, but continuous variation is the rule over much of the planet, with the genetic characteristics of the various regions changing smoothly in the geographical space.

Table 3 Genomic estimates of F_{ST} for the global human population

Number of markers	*Samples*	F_{ST}
599,356 SNPs	209 individuals from 4 populations: Caucasian, Chinese, Japanese, Yoruba	0.13
1,034,741 SNPs	71 individuals from 4 populations: Caucasian, Chinese, Japanese, Yoruba	0.10
1,007,329 SNPs	269 individuals from 4 populations: Caucasian, Chinese, Japanese, Yoruba	0.12
443,434 SNPs	3845 worldwide-distributed individuals	0.052
2,841,354 SNPs	210 individuals from 4 populations: Caucasian, Chinese, Japanese, Yoruba	0.11
243,855 SNPs	554 individuals from 27 worldwide populations	0.123
100 *Alu* insertions	710 individuals from 23 worldwide populations	0.095
1,447 CNVs covering 12% of the genome	270 individuals from 4 populations: Caucasian, Chinese, Japanese, Yoruba	0.11

From Barbujani, G., Colonna, V., 2010. Human genome diversity: frequently asked questions. Trends in Genetics 26, 285–295; where the original references can be found

The genetic differences between populations, around 13% of the global species variance, are small, but not zero. Based on these differences, individuals can often be assigned to populations. By selecting polymorphisms among the most variable of the genome, Witherspoon et al. (2007) could correctly classify most people from different geographical origins. However, the error rate remained substantial even in comparisons between continents, such as sub-Saharan Africa and Europe. The accuracy of the assignment depends on the degree of differentiation between populations, on the number of populations being compared (the more, the higher the error), and on the number of polymorphisms considered (Romualdi et al., 2002; Witherspoon et al., 2007).

On the other hand, the genetic differences between populations are not zero, but they are small. Once the analysis of highly variable polymorphisms has shown that a certain individual has a high probability of belonging to a certain population, predicting that individual's genotype at other loci is problematic because different polymorphisms show different patterns of variation. Despite that difficulty, and although few statisticians would try to discriminate groups when the variance within them is 8–9 times as large as that between them, identifying even moderately differentiated genetic groups could be of potential relevance for clinical practice (see Section Races in Medicine). To be useful, however, this exercise should produce a stable classification, that is, a consistent list of biological groups, independent of the markers studied. So far, that has not been the case.

A popular approach to this question is based on an algorithm, STRUCTURE, assigning individual genotypes to an arbitrary number of groups, k. Various k values are tested, and their likelihood is eventually estimated. In the first, and most influential, worldwide analysis based on STRUCTURE, Rosenberg et al. (2002) typed 377 Short Tandem Repeats (STRs) in 1056 individuals from 52 populations. They recognized six clusters, five of them corresponding to continents or subcontinents, and the sixth to a genetic isolate in Pakistan, the Kalash. In general, individuals of the same population fell consistently in the same cluster, or shared similar membership coefficients in two clusters. The authors concluded that self-reported ancestry contains information on DNA diversity, and hence that an objective clustering of genotypes is possible, if large amounts of data are considered.

In fact, clustering is possible, but it is not consistent across studies. In a subsequent paper based on a larger assemblage of data, the same authors failed to confirm the Kalash as a separate unit; instead, the Native American populations were this time split into two clusters (Rosenberg et al., 2005). The Kalash resurfaced as a distinct group when 15 Indian populations were added to the analysis, leading to the identification of seven clusters, with most populations of Eurasia now showing multiple memberships. In these studies, all African genotypes

formed a single group, a result that may point to a weakness in the methodology, since there is broadly replicated evidence of a deep population subdivision within Africa (Hunley et al., 2009). Indeed, when the same dataset was analyzed by a method that highlights zones of sharp genetic change or genetic boundaries, Africa appeared to be subdivided into four groups, and each American population formed an independent group, giving a total of 11 (Barbujani and Belle, 2006). In Jakobsson et al.'s (2008) study of more than half a million SNPs, STRUCTURE indicated different clusterings if the SNPs were individually analyzed or if they were combined to form haplotypes. In turn, both inferred clusterings were inconsistent with those inferred from CNVs in the same individuals.

In practice, no matter whether inferred from protein variation or from recent genomic analyses, the proportion of human genetic variance due to differences between populations is modest. Differences exist and have significant evolutionary implications, but it is an error to consider them typical of populations, and not of individuals, because genetically different individuals coexist in the same population. When the number of markers is large, many dissimilarities are detected, and a fraction of these are likely to achieve statistical significance. However, minor differences in the markers considered, in the sample distribution, or in the method of analysis, lead to different clusters.

An illustration of the consequences of this aspect of human diversity comes from comparisons of complete individual genomes. Among the first people whose genome was entirely sequenced are James Watson and Craig Venter, both U.S. geneticists of European ancestry. Their genomes share 1 715 851 SNPs, which is less than each of them has in common with the genome of the Korean scientist Seong-Jin Kim (1 824 482 and 1 736 340, respectively) (Ahn et al., 2009). The fact that a person of Asian ancestry (Kim) is genetically intermediate between two persons of European ancestry (Watson and Venter) does not mean that on average Europeans are genetically closer to random Koreans than to each other, but highlights the limitations of such coarse categorizations. Populations are structured in the geographical space, Asians and Europeans appear well separated in analyses of population structure, but when it comes to predicting individual DNA features, labels such as 'European' and 'Asian' are misleading, because members of the same group, Watson and Venter in this case, may be very different. If what matters for future research is whether by racial labeling we can approximate what is in a person's genome, it is already clear that the answer is no (Xing et al., 2010). As a matter of fact, the best way to know what is in a person's DNA is to study that person's DNA. In the past, this task was technically challenging, but now it is both feasible and cheap.

Comparisons with Other Species

We are not alone on Earth; examining patterns of population diversity in our own and other species may help us put human diversity in broader evolutionary perspective. Among primates, humans have the lowest levels of DNA diversity, in two different ways. First, comparisons of X-chromosome sequences show that individual variation in humans is half that observed in gorillas, and less than one-third that observed in orangutans and chimpanzee (Kaessmann et al., 2001). Second, F_{ST} values estimated between gorilla ($F_{ST} = 0.38$) and chimpanzee ($F_{ST} = 0.32$) populations are roughly three times as high as most human estimates ($F_{ST} \leq 0.13$, Table 3). Thus, not only are individual differences in humans much smaller than between individuals of other primate species, but also these small differences are mainly accounted for by individual differences within populations. In other words, we are subdivided into more closely related populations than any of our evolutionary relatives (with the possible exception of bonobos, *Pan paniscus*), despite the fact that humans occupy a much broader geographic area.

Templeton (1998) extended this comparison to 12 large-bodied, highly mobile mammals. Two such species (East African Buffalo and Kenyan Waterbuck) show smaller between-population diversity than humans. However, these species are not cosmopolitan like ours, but dwell in restricted geographical zones. All other species compared, including elephant, gazelle, and gray wolf, show higher, or much higher, differentiation among populations and groups, with the values of those variance components reaching 80% of the total. The limited degree of differentiation among human populations does not suggest a history of long-term isolation and differentiation, which was likely the case for other mammals.

Dogs and horses are sometimes cited as examples of species subdivided in clear races or breeds. In comparing them with humans, one should keep in mind that breeds evolved in domesticated animal as a result of human-driven artificial selection only in the last 10 000 years or so, whereas human populations might have diverged for many tens of thousands years. Despite that, F_{ST} among dog breeds is nearly three times as large as in humans, around 0.35 (Von Holdt et al., 2010). F_{ST} has not been estimated yet for the whole horse species, but for both dogs and horses estimates of linkage disequilibrium are available—that is, a measure of the nonrandom association of alleles along the chromosomes. Population-genetic theory demonstrates that linkage disequilibrium increases after a sharp reduction of population size, such as that resulting from the selection of a few individuals to start a new breed (under artificial selection) or whenever a population evolves in isolation (under natural conditions). Levels of linkage disequilibrium are highest in dogs, intermediate in horses, and least in humans. These figures also depend on the distance along the chromosome between DNA regions; considering, for example, regions separated by 0.2 million bases, linkage disequilibrium in dogs is six times as large as in humans, and in horses four times as large as in humans (Wade et al., 2009).

In short, data on genome diversity in mammal species, either evolving under natural conditions (such as elephant, chimpanzee, and orangutan) or under artificial selection (such as dog and horse) show significant differences between these species and humans. Humans show the highest degree of allele sharing between populations, even distant ones; several features of human DNA diversity seem to indicate a comparatively recent origin from a small number of founders, who differentiated while dispersing to colonize the whole planet, and whose populations often exchanged migrants. This history has produced a pattern of genetic variation that is inconsistent with the existence of independently evolving groups (Hunley et al., 2009).

Races in Medicine

The repeated observation that population affiliation is not a reliable predictor of an individual's specific genotype (Xing et al., 2010), has led to a reconsideration of the utility of terms such as 'race,' 'racial differences,' and 'ethnic background' as proxies in medical decisions (e.g., for decisions on the kind of treatment, dosage, etc., but also for diagnosis). Schwartz (2001) wrote that there is no plausible biological justification for racial distinctions. Risch et al. (2002) responded by claiming that they could demonstrate the validity of racial self-categorization 'from an objective perspective.' In fact, they proposed verbal arguments supporting the view that each continent corresponds to a distinct genetic cluster of populations. In addition, they defended the status of race for Hispanics, a group composed of people of different origins who have two features in common, being immigrants in the United States and speaking Spanish, neither of which has a genetic basis. Despite all these problems inherent in using race as shorthand for a cluster of people supposedly sharing the same biological characteristics, racial categories are routinely employed by U.S. medical doctors, scientists, and community health workers. On 10 July 2012, a PubMed search of scientific literature using the term 'human races' returned 133 129 items, and about 1000 new entries are being added every month.

As mentioned above, one reason why medical doctors hesitate to abandon racial categorizations may be the fact that different diseases have different prevalence in different populations. Actually, much like any other allele, alleles associated with genetic pathologies or predisposition to diseases do vary in frequency. Because these frequencies are low, these alleles tend to show a more restricted geographical distribution, and many of them can be regarded as population-specific; examples include many hemoglobin variants, the *HEXA* mutation causing Tay-Sachs disease in Ashkenazi Jews, and the Mendelian alleles associated with the so-called Finnish disease complex. However, in all these cases, the pathologic alleles are carried by a small fraction of the chromosomes in the population, typically less than 1.5%. Defining Ashkenazi Jews as the genetic group carrying the Tay-Sachs disease allele would mean to exclude from the group the 98% of them who do not carry the *HEXA* mutation.

While recognizing that distinguishing groups of humans from each other on genetic grounds is problematic, Harpending (2007) argued that the race concept is indispensable to understand the causes of human disease. He then proposed to regard as races human groups among which genetic differences exist. Since some degree of genetic differentiation has been found between any two sets of humans compared so far, be they arbitrary or defined by geographical, cultural, or epidemiological criteria, Harpending's definition implies that any human population is a race. The meaning of words is conventional, and so one could be tempted to settle the issue by deciding to henceforth use race and population as synonymous. However, that does not seem a good idea. In science, and not only in science, communication is possible when all communicators accept some common criteria. 'Thank you' denotes a higher level of gratitude than 'Get lost.' One may decide to express his gratitude by saying 'Get lost,' but shifting to that convention will harm his social life. Giving the status of race to all populations does not seem to make much more sense.

It is possible that with time the interest in racial categorization will decline also clinical practice as well. Ever since the development of a scientific approach to medicine, the purpose of therapeutic strategies has been to cure the 'average patient,' but this average patient is a statistical abstraction. Real patients have different disease risks and respond differently to pharmaceutical treatment. In a sense, then, the so-called racial medicine is an attempt to come to terms with these differences and somehow take them into account. But it is a scientifically superficial attempt, based on the erroneous assumption that people classified in the same racial category are genetically homogeneous. Contrary to the claim that racial stereotypes capture some meaningful aspects of biological variation, the available data suggest that a good way to predict whether certain individuals will have certain health risks or will benefit from pharmaceutical treatment is to study their genes. Individuals vary in their drug response as a consequence of variation at several genes coding for the enzymes responsible for drug metabolism. In a classical study of CYP2D6 (Ingelman-Sundberg et al., 2007), the best-known drug-metabolizing enzyme, Chinese and Swedes were shown to differ in their average rates of metabolism, with an excess of slow-metabolizing individuals in the Swedish sample. However, both populations included the whole range of possible phenotypes, from poor to ultra-rapid metabolizers (Johansson et al., 1991). Therefore, a racial-medicine approach consisting in looking for a dosage of the drug that will make everybody happy in Sweden or China is a waste of time. What is conceivable and, in the future, hopefully feasible, is to identify the alleles responsible for individual variation, hence giving to each person, no matter whether Chinese or Swedish, the drug dosage that fits the individual therapeutic needs. This is part of a recent, serious attempt to replace the use of proxies such as gender, age, and race in medical decision making by a multitude of integrated data characterizing individuals at the molecular level (Committee on a Framework for Developing a New Taxonomy of Disease, 2011).

Racial Variation in Intelligence?

Very little can currently be said about the inheritable bases of variation in cognitive abilities. Biological determinism, that is, the idea that what we are and can possibly be is written in our genes, reached its most radical modern expression with the best seller *The Bell Curve*. In that book, Herrnstein and Murray (1994), respectively, a psychologist and a political scientist, claimed that intelligence is accurately measured by the Intelligence Quotient (IQ); that the IQ is genetically determined, constant through life, correlated with race, and basically independent of any social or economical factors; and that a 'cognitive elite' of biologically gifted people is endangered by the U.S. social policies, transferring resources from the rich (and therefore intelligent) to the poor, thus favoring a higher fertility of biologically inferior people. Whatever one might think of the political aspects of Herrnstein and Murray's proposal, its biological bases are phenomenally flawed.

In a sense, biological determinism reflects a deep faith in the ability of biology to explain everything. Unfortunately, that faith

is not justified. To stay within the realm of genetics, we understand well how single genes work, and we can predict the occurrence of many diseases caused by single-gene defects. However, most diseases depend on the interaction of many genes and environmental factors. We also have a good understanding of many gene-to-gene and protein-to-gene interactions, but as the number of interacting genes and factors in the environment exceeds a few units, the available models become unsuitable. That is why we cannot predict the onset of Type 2 diabetes, to which at least 36 genes are known to contribute (Herder and Roden, 2011). The onset of most cancers, cardiovascular, and neurodegenerative diseases depends on greater numbers of genes than diabetes. Understanding variation for common traits such as height, weight, or physical performance is clearly more complicated than predicting disease onset (see Weedon et al., 2008), and by far an even more complex task would be to understand the genetic determinants of human cognitive abilities. More than 1500 genes are expressed in the frontal brain cortex and change their level of expression during fetal or infant development (Colantuoni et al., 2011). This means that, even if what we call intelligence depended only on the frontal cortex (which we can safely rule out), to account for its genetic bases we ought to consider thousands of factors – at present, a totally unmanageable number.

The effects of this enormous collection of genes on individual cognitive abilities are just beginning to be investigated. With regard to genetic differences in intelligence between human groups, we just do not know how to start addressing the problem in scientifically respectable terms. Based on what we know, nobody can seriously claim that there is any evidence that social and economic differences between human groups, defined on the basis of race, class or sex, stem from inherited, inborn differences, and hence that social stratification is a fair or inevitable reflection of biological hierarchies.

Tentative Conclusions and Future Prospects

Population-genetics theory and empirical data show that genetically differentiated groups tend to evolve when genetic drift affects populations connected by little (or no) migratory exchanges. In that case, the populations' internal diversity will decrease as alleles are lost by chance and are seldom reintroduced by gene flow; because in each population different alleles are lost and different mutations occur, genetic boundaries may arise. Conversely, boundaries are unlikely to develop if the effects of gene flow exceed those of drift.

All humans are genetically different, but our species shows lower degrees of interpopulation differentiation than most other mammal species. Geographical patterns in human genome diversity exist, but each human population harbors a large share of the species' diversity; that diversity is largely continuous in space, rather than interrupted by boundaries. This probably means that subdivision and isolation were more the exception than the rule in the human past. Taken together with the fact that no agreement has ever been found on the number and definition of human races, this finding casts radical doubts on the race concept as a useful tool for describing human biodiversity.

Now that hundreds of whole genome sequences have been studied, there is no reason to suspect that the comparatively weak geographical structure of humans might be an artifact, due to our limited ability to detect the alleles that make us, apparently, so different. Thus, if we are to understand our demographic history, a good starting point is to ask what combination of evolutionary factors has led to the coexistence in the same populations of a broad spectrum of genetically different individuals. This way, we might be able to reconstruct aspects of our migratory history that still escape us. The fossil record documents an origin of anatomically modern humans in Africa, more than 100 000 years ago. We do not know yet if they expanded through Palestine in a single wave, some 60 000 years ago (Ramachandran et al., 2005; Liu et al., 2006), or if there was an earlier exit through a Southern route, that is, through the horn of Africa into Southern Asia and Australia (Lahr and Foley, 1994). A better understanding of the times and tempos of dispersal from Africa is crucial for testing the hypothesis of a possible (if limited) hybridization between anatomically archaic and anatomically modern humans, recently supported by the publication of a draft sequence of the Neandertal genome (Green et al., 2010). Finally, different hypotheses exist on the details of the peopling of several areas of the world, and by carefully investigating current and past genomic diversity we might be able to reject some of these hypotheses.

Envisaging our species as genetically subdivided in differentiated races is of no use for addressing questions of this kind, and leads to errors in clinical practice. Still, race remains an important component of our social and psychological world. This component affects human interactions and social policies, and will not vanish just because some scientists say it should. In a sense, then, races do exist, and they should be kept into consideration. However, on the basis of what is known, they exist only in the sense that the labels we stick on ourselves and on the others have practical consequences, even if they do not correspond to empirically identifiable biological realities (Glasgow, 2009). Should new biological evidence emerge, this conclusion will have to be reconsidered. However, at present, the burden of the proof is definitely on those supporting the existence of a racial structure in the human species.

This article is a revision of the previous edition article by T. Duster, volume 19, pp. 12703–12706, © 2001, Elsevier Ltd.

Abstract

This article discusses the research on race identity. We examine some of the more significant behavioral research traditions that have addressed this issue. Issues such as the development of racial identity, white identity, and current and future trends in the broader study of identity are also addressed.

Politics and Identity Politics

In every society, racial identity is generated by massive historical, economic, and political forces that far transcend the level of individual choice (Banton, 1977; Miles, 1989). Racial identity is socially constructed in a society as a consequence of these forces. By social construction, we refer to the fact that a society defines racial groups and defines who is in them. In attempting to explain the differences between people, Europeans as far back as the sixteenth century attempted to classify people according to skin color (Jordan, 1968). Though the concept of race as we know it today was slow to develop, by the nineteenth century, relatively clearly defined racial groups existed throughout much of the world. In the worldwide quest for white supremacy, those with the power to define themselves and others thrust a racial label on themselves, 'white,' and a contrasting label on those they considered 'not white,' such as blacks, Indians, and others. This was the result of politics and differential societal power, not biological or medical science.

Indeed, there is overwhelming evidence that race is arbitrary, shifting, and often biologically and sociologically inconsistent and contradictory (Corcos, 2014). A consortium of leading scientists across the disciplines from biology to physical anthropology issued a 'Revised UNESCO Statement on Race' in 1995 – a definitive declaration that summarizes 11 central issues and concludes that in terms of 'scientific' discourse, there is no such thing as a 'race' that has any scientific utility: "… Many scholars now acknowledge the fact that the biological concept of race as a means of characterizing human populations is so flawed that it is no longer a scientifically valid concept. In fact, the statement makes clear that the biological concept of race as applied to humans has no legitimate place in biological science" (Corcos, 2014; Katz, 1995: pp. 4, 5).

However, the power of social construction leads to a social definition of racial groups and who is in those groups (Omi and Winant, 1986). This leads people to come to identify with a group. Again, a group label is thrust upon people, as a consequence of marking people as different from one another and as a vehicle for achieving group solidarity (Kelley, 1997; Fredrickson, 1995; Crenshaw et al., 1995). There is an important distinction between being labeled as a member of a particular group and psychologically identifying with that group. For example, while one may be a member of the Jones family, one may not feel a psychological connection with the Jones family. Thus, racial labeling is not necessarily the same as racial identification.

Racial Identity and Individual Identity

Assimilation into a racial identity involves two components: racial group identification and racial group consciousness. Racial identity is defined as one's sense of self that is related to racial group membership (Belgrave et al., 2000). Racial identity is a multidimensional construct that includes the strength of one's identification with one's racial group, a sense of attachment to other group members, an evaluation of group membership (e.g., how much the individual likes or dislikes being white, for example) and may include group-relevant attitudes and behaviors (Allen et al., 1989; Phinney, 1996; Sellers et al., 1997). Foundational studies of racial group consciousness argued that group consciousness also implied an action orientation and a set of political beliefs attached to the racial group (Gurin et al., 1980). In other words, some argue there is an ideological meaning attached to a racial identity (Gurin et al., 1980).

There is a large body of research going back to the Clark and Clark (1947) doll studies that has investigated a set of constructs that purport to measure racial identity. They are sometimes labeled differently, such as self-consciousness, racial group identification, racial group perceptions, and acculturation (Baldwin and Bell, 1985; Broman et al., 1988; Landrine and Klonoff, 1996a,b; Parham and Helms, 1981; Utsey, 1998). A key commonality for many of these constructs is the sense of strong psychological and emotional connection to being a member of the racial group. For many scholars, this sense of strong psychological and emotional connection defines racial identity (for example, see Broman et al., 1988; Cross et al., 1998; Landrine and Klonoff, 1996a; Sellers et al., 1997). Thus, an individual who does not feel this strong sense of emotional and psychological connection is commonly regarded of as not identifying with the racial or ethnic group.

The Development of Racial Identity

Two of the most important factors in the development of racial identity are racial discrimination and interracial contact. Several studies have focused on racial discrimination and its

impact on African-Americans and other minorities (Broman et al., 2000; Chou and Feagin, 2014; Essed, 1991; Feagin, 1991; Kessler et al., 1999). Several studies have shown that racial discrimination is relatively pervasive (Broman, 1996; Broman et al., 2000; Essed, 1991; Feagin, 1991; Kessler et al., 1999; Swim et al., 2003). Racial discrimination is thought to reinforce the racial label applied to an individual and to groups, and the boundaries between groups, and to also increase the tendency to racially identify with the group (Branscombe et al., 1999).

Interracial contact is also an important factor in racial identity. Studies in the tradition of the 'contact hypothesis' have long suggested that interracial contact affected both majority and minority groups (Allport, 1954; Deutsch and Collins, 1951; Wilner et al., 1955). Early studies found support for the hypothesis, but more sophisticated studies found more limited effects (Ellison and Powers, 1994). Scholars have also noted the reverse: the lack of interracial contact corresponds to racial insulation. Studies examining this phenomenon have found that the lack of interracial contact, or racial insulation, affects both Black self-esteem and racial identity (Broman et al., 1989; Rosenberg, 1979). The insulation hypothesis argues that because of the segregation in US society, many minorities are insulated from the negative esteem, racism, and discriminatory behaviors of Whites (Rosenberg, 1979; Simmons, 1978). The significant, day-to-day interactions that many minorities have occur in primarily minority contexts. It is only in dissonant contexts, where minorities are in primarily White contexts, that they are subject to the direct expression of racial hostility, experiencing themselves as 'marginal,' and more likely to compare themselves to Whites rather than to other minorities. Thus, interracial contact – the amount and the context – is argued to have direct impact on racial identity.

Building on the idea that people develop identities based on how other people see them and treat them, early researchers focused on low self-esteem and self-hatred as key components of black identity (Horowitz and Murphy, 1938; Clark and Clark, 1947). Given that African Americans commonly experienced exclusion and discrimination by whites and were generally stigmatized in American society, blacks were thought to internalize this societal rejection and devaluation leading to self-hatred and low self-esteem. This view of black identity came under intense criticism in the wake of the black power movements of the 1960s, and during the 1970s researchers shifted to an emphasis on resilience and formulated new theoretical models that emphasized the development of strong, healthy black identities in opposition to white racial oppression. Cross (1971, 1991), for example, proposed a model of Nigrescence by which African Americans proceeded in five stages to shift from a non-Afrocentric to an Afrocentric identity. The five stages were preencounter, encounter, immersion-emersion, internalization, and internalization-commitment and Hall et al. (1972) developed a 55-item questionnaire to measure them.

Parham and Helms (1981) built on Cross's work, theorizing that the critical period for identity formation was late adolescence and young adulthood and developing the 30-item Racial Identities Attitudes Scale to measure the preencounter, encounter, immersion-emersion, and internalization stages of Nigrescence. They argued that progress through the successive stages was not inevitable and that identity formation could stagnate or regress back to earlier stages of development, a process they called recycling. Milliones (1980) saw black identity developing in four stages – preconscious, confrontation, internalization, and integration – and developed the 65-item Developmental Inventory of Black Consciousness (DIBC) to assess them. Research done using the DIBC found that high preconscious scores (indicating low black consciousness) were associated with low self-esteem and dissatisfaction with appearance (Smith et al., 1991) and that high confrontation scores (indicating high black consciousness) were associated with unwillingness to share information with other African Americans (Taylor and Rogers, 1993).

Baldwin (1985) developed his own theory about the structure and content of black personality and created the 42-item African Self Consciousness Scale (ASC) to assess individual awareness of African identity and culture, the degree to which African survival is recognized as a paramount goal, the extent of appreciation for African institutions and artifacts, and awareness of people and things that are African and non-African. Not surprisingly, students attending black colleges and universities that tend to have higher ASC scores than those attending predominantly white institutions (Baldwin et al., 1987). Jackson et al. (1988) included a variety of items on the National Survey of Black Americans to assess feelings of closeness to a variety of different kinds of African Americans and used them to create a scale of black identity. Older, less-educated, urban African Americans tend to score high on this scale, as do blacks who came of age in schools, neighborhoods, and workplaces characterized by high proportions of African Americans (Broman et al., 1989).

Demo and Hughes (1990) factor analyzed items from the National Survey of Black Americans and argued that African American identity had three components: closeness, black separatism, and black group evaluation. Closeness indicates the degree to which respondents feel that their feelings and thoughts are similar to those of other African Americans; black separatism indicates the extent of commitment to black culture and inclination to restrict social relationships to other African Americans; and black group evaluation is the degree to which respondents believe that African Americans display positive characteristics. They found that integration into mainstream American society is associated with less in-group solidarity but that mainstream integration and higher economic status enhance the positive evaluation of African Americans.

In their analysis, Allen et al. (1989) identify five dimensions of black racial identity: closeness to elite African Americans, closeness to common African Americans, positive stereotypes, negative stereotypes, and black autonomy, with the latter being close to the black separatism component of Demo and Hughes (1990). According to Allen et al. (1992), lower-status African Americans hold more negative stereotypes about their group and feel closer to elite blacks than those of higher status, but status had no effect on black autonomy or belief in positive stereotypes. In contrast, higher-status African Americans were less supportive of black autonomy and felt distant from lower class members of their group.

Sanders-Thompson (1991, 1995) also proposes a multidimensional model of black racial identity, though not one that is developmental in the manner of Cross (1971, 1991). Her model consists of four components. The physical dimension assesses the degree of acceptance of African American physical attributes; the cultural dimension measures awareness of black cultural and social practices; the sociopolitical dimension indicates awareness of black social and political issues; and the psychological dimension reflects pride and belongingness to African Americans as a social group. Her Multidimensional Racial Identification Scale presently includes 30 items (Myers and Sanders-Thompson, 1994). She found that physical identity was associated with experiences of racism and greater racial socialization within the family. Psychological racism was associated with experiences of discrimination and greater involvement in the black community; and sociopolitical and cultural identity both reflect greater community involvement and family socialization (Sanders-Thompson, 1991, 1994, 1995).

Like Sanders-Thompson, Sellers et al. (1997) propose a multidimensional model of black racial identity that incorporates four components: racial centrality (whether race is a core part of individual identity over time), racial salience (whether race is an important part of an individual identity at a point in time), racial ideology (philosophical beliefs about how African Americans should relate to American society), and racial regard (evaluations about an individual's own race). The ideology dimension has four subscales: nationalist (emphasizing the uniqueness of African origins), oppressed (emphasizing commonality with other disadvantaged groups), assimilationist (emphasizing similarities between blacks and other Americans), and humanist (emphasizing the similarity of all human beings). They found that respondents who reported a black best friend displayed high values on the centrality and nationalist scales and lower values on the assimilationist and oppressed scales.

In their evaluation of the various black racial identity scales, conclude that "there is no consensus as to the best way to conceptualize or measure racial identity in African Americans." For members of racial groups other than African-Americans, there has been little research on how they might racially identify, though Phinney (1992) has proposed a general model of ethnic identity. There is more research upcoming on white racial identity, and the literature on acculturation is, at least peripherally concerned with Latino identification. In the past, it is plausible that there was simply no justification for the pursuit of such a research question for whites and other racial or ethnic groups.

White Identity

In recent years, the concept of white racial identity has come into increasing focus as a basis for a research agenda. Blumer's (1958) classic article reframed race as a structural relationship between competing group interests. This position was adopted and developed by an early entry into this field, David Wellman's 'Portraits of White Racism' (1993). Roediger (1991, 1994), Frankenberg (1993), Allen (1994), Jacobson (1998), Lipsitz (1998), and Perry (1998) have each examined the ways in which white privilege is embedded in a faceless and taken-for-granted normalness of white identity. Twine and Warren (2000) have assembled an anthology in which they bring to greater consciousness the ways in which researchers in racially stratified societies ignore at their peril the subject world of race as an integral feature of methodology, largely through the racial identity of subjects and researchers. However, as yet, the field of white racial identity lacks a coherent theoretical focus and a body of empirical research. This is something we look forward to in the near future.

The Future of Racial Identity: How Does 'Mixed' Race Figure In?

A recent development in this field of study concerns mixed race. Heretofore there was no such thing in the United States, as people were labeled according to a strict protocol. This meant that people were of one race or another; there was no such thing as a mixed race person. The infamous one-drop rule is an example of this. Pele with a drop of black blood were considered to be black. However, recently, a number of scholars of race have noted the increasing use of the category of 'mixed race' as the self-identity of a younger generation, mainly of relatively privileged and middle-class persons. Maria Root (1996) has culled a collection of essays that deal with identity construction along ethnic and racial lines and further explores these issues well beyond the black and white focus that has riveted much of this literature. The difference between 'individual choice' of a racial identity as opposed to having a racial identity 'imposed' by the state and/or the obdurate empirical reality of a group consensus (based primarily upon phenotype-stereotype) is profound, yet variable over time and place. This focus on mixed race is currently in vogue and is an example of the fact that there are concrete economic, political, social, and sometimes psychological benefits to choosing certain identities. That is why scores of thousands of light-skinned 'blacks' under slavery in Brazil, Jamaica, and the United States chose to 'pass' as white (Small, 1994). For parallel reasons, thousands of persons in the United States have attempted to reclassify themselves as Native American or Latino or African American to benefit from affirmative action laws. It remains to be seen if this interest in mixed race will continue into the future.

Race: Prespectives and Crime

Michael J Leiber, Department of Criminology, University of South Florida, Tampa, FL, USA
Jennifer H Peck, School of Criminology and Criminal Justice, Florida Atlantic University, Boca Raton, FL, USA

Abstract

The empirical and theoretical literature surrounding the relationship between race and crime has found that in general, minorities (especially Blacks) are overrepresented as offenders compared to their representation in the general US population. Two potential explanations for this racial disparity are differential offending and selection bias. This article describes various theoretical perspectives of the relationship between race and crime, with a primary focus of why minorities may commit more crime/more serious crime and are overrepresented as offenders through both the juvenile and adult justice system.

Introduction

Race/ethnicity has generated an enormous amount of research and debate in criminology (e.g., Leiber, 2003; Wang and Mears, 2010). One factor that underlies much of this activity is the overrepresentation of minority youth and in particular, Blacks, in both the criminal and juvenile justice systems. This article provides a discussion of explanations for the social control of minorities throughout both justice systems. The next section of the article provides official statistics concerning the relationship between race and crime. The next section discusses the theoretical perspectives for understanding why minorities commit more crime or more serious crime. This explanation is known as the differential offending perspective. The final section focuses on the differential selection or selection bias argument. Theoretical perspectives of race and crime that center on potential racism or bias that results in minority representation throughout juvenile justice and criminal justice systems are discussed to conclude the article.

Official Statistics on Race and Crime

According to information provided from the 2010 US Census, the overall Hispanic population surpassed the Black population as the largest minority group in the United States for the first time since the US Census began its data collection. Hispanics comprised 16% of the US population, while 84% of individuals identified as non-Hispanic, but other racial categories. Specifically, Whites represented 64% of the general US population while 12% of all individuals identified as Black. Asians/Pacific Islanders (5%), American Indians/Alaskan Natives (1%), other racial groups (1%), and individuals of two or more races (1%) were also represented (U.S. Census Bureau, 2000). When the juvenile population is disaggregated from the overall US population, White youth represented 76% of all youth up to 17 years old, while Black youth comprise 16% in 2012. American Indians and Asians represented 2 and 6% of all juveniles in 2012, respectively (Puzzanchera et al., 2013).

For the purpose of this article on race perspectives and crime, it is important to understand the representation of different racial/ethnic groups in the general US population in order to compare them to the proportion of racial/ethnic groups involved in crime. For example, the FBI's Uniform Crime Reports (UCR) is one form of crime measurement that collects data on crimes reported to the police across the United States. **Table 1** presents the UCR's count and percentage of violent crime and property crime arrests in 2012 for Part 1 index crimes by race. Part A includes arrests for individuals 18 years and under, while Part B includes arrests for ages 18 years and older.

As shown in Part A of **Table 1**, data from the 2012 UCR shows that White youth are underrepresented in arrests across both violent and property crime arrests compared to their representation in the general population. In particular, White youth represent 47% of all violent crime arrests, and 62% of all property crime arrests. Black youth, however, are overrepresented in arrests across both offense types. Black youth represent 51% of all violent crime arrests and 36% of property arrests. For the most part, American Indian/Alaskan Native youth are arrested at a similar proportion to their representation in the general youth population, while Asian/Pacific Islander youth are underrepresented in UCR violent crime and property crime arrests.

To some degree, Part B of **Table 1** presents similar results as Part A for individuals who are arrested over the age of 18 years. Across both violent and property arrests, White adults are arrested similar to their representation in the general population (60–69%). Black adults, however, are consistently

Table 1 Arrests in 2012 for part 1 index crimes by race

overrepresented in across both arrest categories. In fact, the proportion of all arrests for Blacks is at least two times larger for property crime, and three times larger for violent crime than in the general population (12%). American Indian/Alaskan Native adults are slightly underrepresented in violent and property crime arrests, while Asian/Pacific Islander adults are arrested at comparable proportions to the general population across crime types.

According to FBI arrest statistics, over 1.6 million youth under the age of 18 years were arrested for either violent, property, or other (e.g., vandalism, disorderly conduct) types of crimes in 2010 (Puzzanchera et al., 2012). Out of the 1.6 million youth who were arrested, over 1.3 million of those youth were subsequently referred to the juvenile court (Puzzanchera et al., 2012). **Table 2** presents the racial characteristics of cases handled by the juvenile court in 2010.

Of person, property, drugs, and public order cases referred to the juvenile court, White youth represent 64% of all referrals, while Black youth are overrepresented with 33% of all referrals. Out of all of the cases that were detained, 40% were Black youth, and 57% were Whites. Black youth also represented 37% of all cases that were formally charged, compared to 60% of Whites. Throughout these three stages, Whites are consistently underrepresented within the juvenile justice system, while Blacks are overrepresented. Native American and other youth are either equally distributed or underrepresented compared to their representation in the general population. With regard to the adjudication stage, White youth are slightly more represented at adjudication compared to earlier proceedings (i.e., detention and formal charging), as they are the largest racial group to be adjudicated delinquent (62%). Recall, although, that White youth comprise 76% of the overall juvenile population, therefore they are underrepresented throughout these stages. Once again, Black youth are overrepresented at the adjudicatory stage, as they make up 35% of all youth who are adjudicated.

In addition, data are provided on a yearly basis from the Office of Juvenile Justice and Delinquency Prevention (OJJDP) for three potential outcomes at judicial disposition: probation (community supervision), out of home placement (residential placement), and other (not included). Across racial groups, Black youth more often received the most severe outcome of residential placement (39%) compared to probation (32%). Both Native American and Other youth were either under or similarly represented at both dispositional outcomes, and were equally likely to receive either community sanctions or residential placement.

It is also important to note that there are a large number of youth each year who are removed from the juvenile court and transferred/waived to the adult court. While the percentage of all cases waived is relatively small (0.4%) approximately 5900 juvenile cases were waived to adult court in 2010. Of those waived cases, disparities across racial groups were once again found, as minorities in general represented 48% percent of all waived cases, while Blacks alone represented 45% of all youth waived. Overall, there is considerable evidence that race disparities occur throughout all stages of juvenile justice proceedings, as Black youth are consistently overrepresented throughout the juvenile justice system across all other racial groups.

While **Table 2** described the representation across racial groups through various stages of juvenile court proceedings, **Table 3** presents counts and percentages of federal defendants handled by the US District Court in 2010 by race and ethnicity. However, a limitation of **Table 3** compared to earlier tables is that all racial groups exclude individuals who are also of Hispanic or Latino origin (because they constitute their own

Table 3 Federal defendants handled by the US District Court in 2010 by race

	White[a]	*Black*[a]	*Hispanic*	*AI or AN*[a,b]	*Asian or NH or OPI*[a,b]	*Other*[a]
Charged	17 021 (21)[c]	14 201 (18)	45 333 (57)	1217 (2)	1138 (1)	255 (1)

Data source: Bureau of Justice Statistics, based on data from Administrator Office of the US Courts, Probation, and Pretrial Automated Case Tracing System (PACTS), fiscal year 2010.

category in Table 3). Therefore, the counts and percentages included in Table 3 may be underestimated compared to earlier tables.

Across the six racial/ethnic categories, Hispanics were the largest group that was charged by the US District Court in 2010. Blacks and Hispanics are overrepresented as federally sentenced offenders in the custody of Federal Bureau of Prisons, comprising 37 and 32%, respectively. The next two categories focus on the count and percentage of offenders released from federal prison, then subsequently return to prison within their 3 years of release. Therefore, while Whites comprise 24% of offenders released in 2008, they represent 22% of offenders returning into federal custody. The proportion of Blacks released in 2008 (24%) was smaller than those who returned to custody in 2010 (31%). Hispanics comprised 50% of all offenders released in 2008 from federal prisons, and represented 43% of those offenders who returned 3 years later. The other three racial/ethnic categories are either similarly or underrepresented as offenders within each category discussed until this point.

Table 3 also includes the racial/ethnic characteristics of offenders within the US District Court under post-conviction federal supervision. Of the total number of offenders who were granted supervised release, two potential options are available: probation and parole. Whites represent 35% of all offenders under supervised release, while Blacks comprise 38%, and Hispanics, 22% of this category. When supervised release is disaggregated between probation and parole, racial/ethnic disparities are even more evident, as Whites and Hispanics are more likely to receive the less severe outcome of probation instead of parole, while Black offenders are almost 2½ times more likely to receive parole as a supervised release option than probation.

Theoretical Perspectives of Differential Offending

Most criminological theories have generally failed to pay specific attention to racial and ethnic differences in the extent and severity of offending. For some, criminological theories are believed to universally apply to all racial and ethnic groups (Hirschi, 1969). More specific, race/ethnic differences in delinquency and criminal offending are seen as the result of individual differences in offenders, family processes, or structural and community explanations (Gottfredson and Hirschi, 1990; Sampson and Wilson, 1995). Still, there are a few race-specific theories and perspectives for understanding why minorities are overrepresented as offenders. The following section will describe how some general and race-specific theories have explained racial differences in offending.

Social and Self-Control Theories

Hirschi's (1969) version of social control theory contends that individuals conform because they have strong affective attachments to parents, stakes in conformity, involvement in conventional activities, and belief in social norms. Conversely, those youth who have weak attachments, low stakes in conformity, little involvement in conventional activities, and/or poor attitudes regarding societal norms are more likely to participate in delinquent behavior. Hirschi (1969) originally argued that the attachment between parent and child is paramount and that the strength of this relationship is the most important factor in deterring delinquent behavior. In other words, it is the quality, and not the quantity, of bonds that determines delinquency. Implicit within Hirschi's (1969) version of social control theory is the applicability of the perspective to all youth, irrespective of race or ethnicity. In fact, Hirschi (1969) stated that he found nothing to contradict the "assumption that the causes of delinquency are the same among Negroes as among whites," and for this reason he stated that "we need not study Negro boys to determine the causes of delinquency" (p. 80).

Gottfredson and Hirschi's (1990) version of the general theory of crime contends that differences in offending between minorities (more specifically Blacks) and Whites are due to Blacks having lower levels of self-control. The lower level of self-control is believed to be by-product of faulty and erratic socialization and supervision provided by parents. Minority families seen as less able to monitor, recognize, and punish deviant behavior in children, and are ineffective at childrearing and in turn minorities commit more frequent and serious crime. Gottfredson and Hirschi (1990) further argue that minority families in general are more likely to include parental criminality, larger family sizes, more single-parent families, and mothers working outside of the home, which are additional examples of why minority youth have lower levels of self-control and an increased probability of involvement in crime.

General Strain Theory

Strain theory and in particular, general strain theory (GST) is another individual-level perspective that has been applied to examine race and ethnic differences in criminal offending. Some have argued that GST can explain racial differences in offending by implying that Blacks and minorities in general experience a disproportionate and qualitative different types of strain that lead to increased levels of involvement in crime. It is argued that Blacks experience different types of strains more than other groups including economic strain (poverty, unemployment), family strain (poor parenting practices), educational strain (problems with students and teachers, poor grades), criminal victimization, racial discrimination, and community strain (living in structurally disadvantaged neighborhoods). Prior research has supported this argument where Black youth who experience welfare and not being happy in their neighborhood are considered types of strains that contribute to delinquent behavior compared to Whites and Hispanics (Peck, 2013).

Social Disorganization Theories

Social disorganization theory is a perspective that emphasizes structural and cultural factors to understand why minorities offend more than Whites. Shaw and McKay (1942) studied deteriorated neighborhoods to better delineate how neighborhood conditions in urban areas created a crime-prone environment. Communities with low socioeconomic status, ethnic heterogeneity (many varied ethnic groups living

among each other), and residential mobility (where people are constantly moving in and out of the neighborhood) are believed to be indicators of social disorganization, which in turn leads to a subculture or the adoption of values that are contrary to those of larger society – gangs and crime. Community characteristics such as low socioeconomic status and residential mobility lead to weak social ties among residents of the community and its institutions such as school or church. Since these communities are unable to provide basic services such as education, health care, and proper housing, there is a sense of disorganization and a lack of social ties and community. Therefore, minorities offend more because they are likely to reside in such communities. Underlying social disorganization theory is a strong economic component.

Sampson and Wilson (1995) offer a revised interpretation of social disorganization theory with a focus on race. More specific, they integrate social disorganization with Wilson's (1987) perspective of economic inequality and racial discrimination to understand minority poverty and involvement in crime. Living in impoverished and segregated communities that evidence unemployment, lack of quality jobs, and family disruption, minorities face structural barriers, isolation, and adapt subcultural values as a means of coping that include a devaluation of educational aspirations, drug use, and crime.

Subcultural Theories

Subcultural theories are considered race-specific perspectives because some perspectives consist of race-related themes that attempt to explain why minorities differentially offend compared to Whites. The most popular subcultural theory is Wolfgang and Ferracuti's (1967) subculture of violence theory that was based on the relationship between race and homicides, specifically the influence of victim-precipitated homicides. It was argued that there was a subculture of violence which does not consider assaults as wrong or antisocial, where physical aggression is socially approved, and where violence is considered normal but often ends in death. The theory articulated seven propositions that encompass the subculture of violence. Some of these propositions include that the subculture is found within all ages of society; however, violence is most prominent in late adolescent and middle age. Violence is not seen as an illicit occurrence, and there are no feelings of guilt. Those in the subculture are not violent all of the time. Throughout the 1970s and 1980s support was mixed, with some studies finding a subculture of violence among Blacks while others failed to find support who argued that poverty was the most consistent predictor of homicide, not race.

Anderson's (1999) 'Code of the Street' is another perspective that has racial and cultural overtones as well as an emphasis on the structural deficiencies of communities. Residing in disadvantaged communities and facing racial discrimination youth and in particular, minority youth adopt a 'street code' to survive. Research suggests that this perspective is applicable to not only Blacks but also Hispanics. The theory has also been applied to victimization in that residents who adopt a 'street code' are at a heightened risk for victimization, above and beyond living in disorganized and violent community.

Life-Course Perspectives

Recently, a few studies have been conducted that examine race/ethnicity and crime from a life-course perspective. Although there are some differences between developmental or life-course theories, these perspectives embody the principle that there is continuity, persistence, and possible desistance in offending (Moffitt, 1993; Sampson and Laub, 2005). In addition, relative offending rates in one age-period link to relative offending rates in others. Continuity in offending is also the hallmark of the most high-rate persistent offenders that are thought to begin their offending careers earlier, have longer careers, and commit more crimes over comparable periods than other types of offenders. While some offenders persist well past the aggregate peak age in offending, most desist in a normative manner in late adolescence/early adulthood (e.g., Moffitt, 1993; Sampson and Laub, 2005). Although distinct, persistence, and desistance are related through a dynamic process involving the consequences associated with the interrelationships between choice, life circumstances, turning points, and criminality (Sampson and Laub, 2005). Ge et al. (2001), for example, examined racial/ethnic differences in offending over time by using data from the California Youth Authority and discovered that up to age 21 years, there were no statistically significant differences in arrest frequencies between Whites and Blacks or Whites compared to Asians. After age 21 years, Blacks, however, were arrested more frequently. Hispanics were also arrested more frequently than Whites but only after age 25 years.

Moffitt's (1993) developmental theory or taxonomy of antisocial behavior argues that Blacks are more likely to be overrepresented as both life-course persistent (LCP) offenders (offend throughout the life course) as well as adolescent-limited (AL) offenders (offend only during adolescent years). Moffitt's justification for this argument is that Black offenders are likely to live in structurally disadvantaged communities that hinder their life chances at success. Thus, Black LCP offenders have experienced inadequate prenatal care, exposure to hazardous toxins, lack of familial attachment and bonds, and disadvantaged school environments. These developmental situations result in poor educational success and limited employment opportunities. Accordingly, Blacks will be more likely to continue offending as adults because they as a group experience higher levels of risk factors (unemployed, single, drinking, and drug use) than do Whites.

In terms of Blacks as AL offenders, Moffitt argues that this type of offender is stuck within a maturity gap that White youth do not experience for as long of duration of time. More specific, Black youth spend more years within a maturity gap because they do not necessarily shift to an 'adult status' with valued adult roles (e.g., employment) and privileges. This delayed entrance into adulthood and conventional adult roles results in Blacks becoming overrepresented as AL offenders, who mimic offending patterns of delinquent peers. These types of offenses symbolize adult social status, such as theft, drinking, and drug use.

Empirical research has found support for Moffitt's explanation of racial differences in offending. For example, results have found that Blacks compared to Whites were more likely to persist in violent offending due to reduced opportunities in economic well-being and employment when in adolescence, supporting an economic maturity gap perspective. Research has also found that for Blacks, certain LCP characteristics of offenders (developmental risk and adverse family situations) were intensified by community disadvantage. This result was not applicable to Whites (Haynie et al., 2008).

Theoretical Perspectives of Selection Bias

Prior research has found that the differential offending explanation alone has not been able to fully account for the relationship between race and crime, specifically how minorities are overrepresented in the juvenile and criminal justice systems (Leiber and Rodriguez, 2011). In particular, the presence of selection bias has evolved into an additional reason why minorities are treated differently compared to Whites. Both overt and covert racial bias and stereotypes have found to account for minorities receiving disadvantaged outcomes compared to Whites (Bridges and Steen, 1998). From these findings, theoretical perspectives of selection bias surrounding the relationship between race and crime have focused on both structural and individual-level factors that influence decision-making of both Black and White offenders.

There are a number of macro-level perspectives of the relationship between race and crime that focus on how community characteristics may influence social control to the disadvantage of minority groups. Contextual indicators such as urbanism, minority representation, structural disadvantage, and racial inequality are some of the factors noted in the literature as being important measures concerning race perspectives and crime. In the following paragraphs, the macro-level perspectives of urbanism and formal rationality (Weber, 1969), minority/racial group power threat thesis (Blalock, 1967), and the theory of inequality and social control (Sampson and Laub, 1993) are discussed in detail.

Urbanism and Formal Rationality

One macro-level perspective that focuses on the influence of community context on crime and court outcomes is a perspective that is characterized by formal and substantive rationality (Weber, 1969). Weber (1969) argued that criminal justice decision-making is based on the interrelationships urbanization and bureaucratization. Specifically, he believed that the economy and legal system are two institutions that guide all individuals within society. The link between both systems is formal rationality, which translates to universally applied laws, rules, and standards in decision-making. Weber (1969) proposed that courts that are located in urban communities make court decisions within the formal rational legal system, which are grounded in the rules themselves. The law is applied equally across extralegal factors (e.g., race, gender, and age) based on legal criteria (e.g., crime severity and prior record) in the formal rational system. Therefore, the amount of discretion given to decision-makers is limited based on the notion that court outcomes depend on legal factors. Few race differences in court outcomes between Black and White offenders should exist concerning their contact and involvement in the criminal justice system.

Compared to formal rationality, substantive or 'informal' rationality is more likely to occur in rural settings, where decision-making is more often based on external values of beliefs, respect, and informal values. Within this type of legal system, discretion is enhanced among decision-makers, which can result in greater disparities among racial groups with regard to involvement in the criminal justice system. Weber (1969) argued that in more rural courts, issues such as racism, stereotypes, and other discretionary factors influence decision-making and result in more disadvantage outcomes for minorities compared to Whites.

However, it has also been argued that urban courts will subject minorities to greater social control than rural courts, based on the argument that the formal rational legal system may not question criminal justice procedures but accept them as binding and rely on factors that may be biased against minorities (e.g., prior record and family status). Since urban courts have a greater number of cases compared to rural courts, decision-makers may classify offenders into 'routine types' that may be based on racial, gender, and class stereotypes (Gaarder et al., 2004). Therefore, while Weber (1969) proposed that race differences will be less likely to occur in urban courts compared to rural jurisdictions, research has also argued that the influence of racial stereotypes may be more prominent in urban settings and result in more severe court outcomes for minorities (especially Blacks) compared to Whites.

Minority/Racial Group Power Threat Thesis

In contrast to Weber (1969) who focused on differences across urban and rural courts based on the degree of bureaucracy in the legal system, Blalock (1967) proposed a macro-level theoretical perspective of race and crime that focuses on how 'racial threat,' 'minority group threat,' and general 'group threat' result to race differences in social control. Two interrelated factors, the size of the minority (e.g., Black) population, and the economic and political situation of the minority group compared to the majority group (e.g., Whites) are argued by Blalock (1967) to result in increases in punitive court outcomes for minorities. More specific, as the proportion of minority residents increase within a community, this situation translates into an increase in competition for economic resources (e.g., jobs, property, and money) and political power of the minority group compared to the majority group. In turn, Whites feel that there is a perceived challenge to their status quo compared to Blacks.

In other words, increases in economic wealth, prestige, and prosperity by Blacks will make Whites (the majority group) feel more threatened. As a result, prejudicial and discriminatory attitudes and practices will be enforced across racial lines to decrease the amount of power by the minority group and perceived notions of threat by the majority group. Overall, Blalock (1967) has found some degree of support depending on the outcome examined. For example, increases in minority populations and political threat resulted in more punitive sanctioning for minorities in the form of prison and jail

sentences (Wang and Mears, 2010) and additional studies have found that minority economic threat resulted in larger police force sizes.

Theory of Inequality and Social Control

One macro-level perspective of race and crime integrated aspects of structural disadvantage, racial stereotyping based on Tittle and Curran's (1988) symbolic threat hypothesis, and the influence of the War on Drugs to explain why minorities receive disadvantaged court outcomes compared to Whites. Specifically, Sampson and Laub's (1993) macro-level of inequality and social control argued that structural indicators of underclass poverty and racial inequality influence juvenile justice decision-making. It was proposed that counties characterized by underclass poverty and racial inequality were more likely to subject youth, especially Black youth, to harsh juvenile court outcomes compared to youth who reside in more affluent counties.

Paralleling Tittle and Curran's perspective (1988), Sampson and Laub (1993) argued that decision-makers will enforce greater social control on populations that threaten middle and upper-class standards. Minority populations, the poor, and the unemployed represent these threatening groups to mainstream American. Decision-makers will perceive these groups are more threatening and subject them to harsh court outcomes. In other words, the term 'the underclass' corresponds to negative perceptions of threatening populations. Furthermore, the perspective states that threatening populations can be disaggregated into more specific groups. Based on the historical context of the War on Drugs, the relationship between race and crime was focused on negative perceptions and racial stereotypes of minorities, especially Black drug offenders. The combination of both aspects of the symbolic threat hypothesis (Tittle and Curran, 1988) and the War on Drugs resulted in Sampson and Laub's (1993) perspective to propose that young, Black male drug offenders pose a specific threat to the general population and will result in race differences in social control.

Overall, the perspective argued that youth who are referred to the juvenile court are more likely to receive severe court outcomes when they reside in counties characterized by underclass poverty and racial inequality. The effect was stated to be larger for Blacks compared to Whites, and drug offenders compared to other types of offenders. For the most part, support for the macro-level theory of inequality and social control is mixed. Research testing Sampson and Laub's (1993) theory has found that race differences in court outcomes emerged regardless of the level of community disadvantage (Leiber, 2003), and both harsh and lenient outcomes were found for minorities compared to Whites once community characteristics were taken into consideration.

While there are a number of macro-level theories that focus on the relationship between race and crime within the selection bias argument, there are also various micro-level perspectives that emphasize the role that individual-level racial stereotypes play in the treatment of minority youth. These perspectives argue that racial biases and stereotypes influence the decision-making of court officers which results in greater social control for minorities. In particular, the symbolic threat hypothesis (Tittle and Curran, 1988), liberation hypothesis (Kalven and Zeisel, 1966), and attribution theory (Albonetti, 1991) are discussed as a few examples of micro-level theories.

Symbolic Threat Hypothesis

As introduced earlier, the symbolic threat hypothesis (Tittle and Curran, 1988) was integrated into Sampson and Laub's (1993) macro-level theory of inequality and social control. One justification for this integration is based on the notion that the symbolic threat hypothesis has a slight focus on how community characteristics influence the perceptions of court actors. The second justification is that the hypothesis primarily emphasizes certain micro-level contingencies of decision-making based on the characteristics of youth (specifically, minority youth) and the social psychological emotions of juvenile justice decision-makers.

The perspective argues that juvenile court actors may perceive minority youth as aggressive, sexual, not taking responsibility for their offenses, lacking discipline, and other negative qualities. These qualities translate into social psychological emotions of fear, resentment, uneasiness, or jealousy against minorities who are referred to the juvenile court. Tittle and Curran (1988) argue that court actors are unable to identify with youth or their offending behavior. In turn, the negative emotions and lack of identification translate to disadvantaged court outcomes of minority youth because these stereotypes and negative emotions influence the decision-making of court officers. However, Tittle and Curran (1988) argued that court decisions are based on the negative perceived thoughts of minority youth, not the actual offending behavior that resulted in minority youth being brought to the juvenile court in the first place. The threat that minorities pose to juvenile court actors is more symbolic than real. The symbolic threats are connected to structural characteristics (e.g., size of the minority population and size of the youth population), and negative emotions of court officers to result in greater social control of Black youth compared to Whites.

Overall, Tittle and Curran (1988) found support for the symbolic threat hypothesis in that counties that were characterized by a large percentage of minority residents and large percentage of youth resulted in harsh court outcomes by court actors against minority youth who were charged with drug and/or sex offenses. It may be that decision-makers viewed minority youth who engaged in these specific offenses as more threatening than youth who were referred to the court for other types of illegal behaviors. Additional support has also been found in the literature that has studied the relationship between race and crime within the juvenile justice system.

Liberation Hypothesis

One micro-level perspective that identifies certain case conditions that influence the decisions of court actors can be tied to racial stereotyping is the liberation hypothesis (Kalven and Zeisel, 1966). Kalven and Zeisel (1966) originally formulated the liberation hypothesis from examining the conditions that affected jury decision-making in sexual assault cases. The hypothesis identifies certain case conditions that result in jurors' ability to 'liberate' back and forth between legal and extralegal influences when determining case outcomes.

The perspective stated that in cases that involve serious crimes (e.g., homicide, robbery, and rape) with strong evidence, discretion is limited and jurors rely on case characteristics and legal criteria. Court actors are more likely to rely on legal factors such as crime severity and prior record when determining case outcomes (Spohn and Cederblom, 1991), and less on extralegal factors such as victim and offender race, gender, and age. Stated differently, decision-makers are less likely to 'liberate' from the legal factors of the case and not base decisions on their own perceptions, beliefs, and even stereotypes. The social control of offenders for serious crimes is more likely to occur based on legal criteria, and less on personal feelings.

With regard to less serious crimes with weak evidence, decision-makers may be more apt to utilize large amounts of discretion, and let personal typescripts and racial stereotypes influence outcomes. In turn, less serious offenses with limited amounts of evidence can result in jurors 'liberating' from the case characteristics and introduce potential extralegal factors into the decision-making process (Horney and Spohn, 1996). Concerning the relationship between race and social control, the liberation hypothesis predicts that minorities will be subjected to increased social control compared to Whites only in less serious cases. This is because discretion is enhanced by decision-makers and race as an extralegal factor within less serious cases will subsequently influence case outcomes to the disadvantage of minority offenders (Spohn and Cederblom, 1991).

Focal Concerns Perspective

The 'focal concerns' perspective is a theoretical model that corresponds to the relationship between race and crime based on the research by Steffensmeier et al. (1998). The perspective specifically focuses on the amount of discretion awarded to court actors and corresponding social control within adult court processing decisions, yet has also more recently been applied within the juvenile justice system. The underlying premise of the focal concerns model is that decision-makers (i.e., judges) have a limited amount of time and information about criminal defendants, and may rely on three focal concerns or attributions involving race, gender, and class stereotypes. The three focal concerns include: (1) the defendants' culpability and blameworthiness based on the seriousness of the offense; (2) society's concern to protect society and the community from the offender; and (3) organizational considerations involving available correctional resources. Even though the three focal concerns are interrelated, Steffensmeier et al. (1998) argue that judges do not have complete information about each type of concern. In turn, judges develop a 'perceptual shorthand,' where they rely on legal factors (e.g., prior record, crime severity) *and* racial stereotypes to determine the outcomes of defendants. In particular, Steffensmeier et al. (1998) found support for their perspective in that young, Black males received more severe sentences compared to any other age, race, or gender category. These results confirmed Steffensmeier et al. (1998) proposed stereotype that young, Black males are often perceived as more dangerous, threatening, and unsuitable for release.

Attribution Theory and Racial Stereotyping

An additional prospective that focuses on the role of racial stereotypes is attribution theory. The perspective proposes that individuals rely upon a set of rules or inferences when explaining individual's behavior (Albonetti, 1991). Albonetti (1991) integrated aspects of the structural organizational approach to decision-making and causal attribution theory to understand judicial outcomes of criminal justice defendants. The structural organizational approach argues that in order for decision-makers to have the ability to make rational decisions, they must be knowledgeable of all relevant information pertaining to the decision and possible outcome alternatives. Decision-makers, however, rarely have complete information to make an informed decision. To reduce the amount of uncertainty and make a more rational decision, actors develop 'patterned responses' that to varying degrees are based on past stereotypes and experiences in determining outcomes (Ulmer and Kramer, 1998).

At the micro-level, Bridges and Steen (1998) proposed that court actors rely on past experiences, cases, offenders, and racial discrimination to influence future case outcomes. Specifically, it was argued that racial bias can be found in different attributions of delinquents, especially the interrelationships between race and class (see also Rodriguez, 2010). Race differences in social control are based on the perceptions that Black youth encompass more negative *internal* attributions (i.e., bad attitude, lack of remorse, lack of cooperation, and failure to take the offense seriously), while White youth may represent more negative *external* attributions (i.e., hostile living environment, poor school performance, and dysfunctional family). Internal attributions of delinquent offenders compared to external attributions are therefore perceived by court officers as being more dangerous, having a higher risk of recidivism, and less amenable to treatment. This would result in more social control and harsher punishments for Black referred to the juvenile court compared to Whites (Rodriguez, 2010). It has also been proposed that certain attributions have been assigned to other minority groups in addition to Blacks. Rodriguez (2010) argued that cultural differences across racial/ethnic groups may result in negative attributions that perceive a Latino youth as prone to violence, more likely to be involved in a gang, and indifferent to juvenile justice intervention (Demuth, 2003).

Conclusion

Minority (especially Black) overrepresentation in arrests and presence in both the juvenile justice and criminal justice systems represent significant issues throughout the field of criminology. While both the differential offending and the race/ethnic selection bias perspectives have been used to explain these occurrences, these explanations have all too often have been pitted against one another. Research has shown that both can explain the disproportionate social control of minorities. Support for each of these positions have led the charge for the need to link factors associated with differential offending (i.e., inequality, subcultural values as adaptations to structural inequities) with the contexts of race and social control in terms of police contact, processing within the court,

and discrimination (Leiber and Rodriguez, 2011). Thus, theory and policy efforts need to focus on the theoretical conditions that contribute to involvement in crime that fuel the reproduction by justice officials of cultural stereotypes of minority offenders, their families, and the neighborhoods in which they reside.

Abstract

This article examines racial relations in the United States, France, and South Africa. After examining the ideas of race, racial group, and ethnic group, the article explores social science theories of racial and ethnic relations – order-assimilation theories and power-conflict theories. The article concludes with an examination of challenges to white European domination of non-European peoples around the globe.

This article examines the reality and development of racial relations in the United States, France, and South Africa. After an examination of the ideas of race, racial group, and ethnic group, the article explores two broad categories of social science theories of racial and ethnic relations – order-assimilation theories and power-conflict theories. Then the article briefly examines typical racial relations in three countries – the United States, France, and South Africa – and concludes with an examination of coming challenges to white European domination of non-European peoples around the globe.

The term *racial relations* denotes relationships between important societal groups socially defined as races. In common usage, this term *race* is ambiguous and taken by many popular and some scholarly analysts to mean that racial relations are not primarily matters of societal power and oppression, but rather mostly involve relationships between groups with relatively comparable societal resources. In many cases, however, racial relations are much more accurately termed *racist relations*. Thus, in areas of the globe where there has been significant European colonization and imperialism – eventually most areas of the globe – systems of racist oppression were created by European colonists and their descendants, who typically enriched themselves substantially at the expense of indigenous peoples' land, resources, and labor. This often brutally executed white Western enrichment became part of the economic foundation for Europe's and North America's long-term economic prosperity and dominant wealth, as well as for the impoverishment of indigenous peoples around the globe (Du Bois, 1965 [1946]).

The Idea of Race

Before the eighteenth century, the English word *race* was used for descendants of a common ancestor, emphasizing kinship rather than skin color or other physical characteristics. By the eighteenth century, this word had evolved fully into its modern racist sense of a category of human beings with distinctive and determining physical characteristics transmitted by descent. In the 1770s, the preeminent Western philosopher Immanuel Kant was the first major scholar to use the term 'races of mankind' (in German) in the sense of physically and biologically distinct 'race' categories. Soon thereafter, the German anatomist Johann Blumenbach laid out a ladder of races that became influential (Hannaford, 1996, pp. 205–207). At the top were the 'Caucasians,' a racist term Blumenbach coined for Europeans, whom he considered to be the superior racial group. Groups lower on his racial ladder were, in order, the Mongolians (Asians), the Ethiopians (Africans), the Americans (Native Americans), and the Malays (Polynesians).

In the late-eighteenth and early nineteenth centuries, Kant, Blumenbach, Thomas Jefferson, and other leading European and North American intellectuals increasingly proclaimed the superior virtues and privileges of being white and of European origin. Educated Europeans and European Americans crystallized the distinction between the 'superior white race' and 'inferior races' and disseminated these views to the general public in their countries and also globally. This *social* construction of races developed dramatically in impact and assertion as Europeans and European Americans expanded their colonial excursions and exploitation of more groups overseas. European and European American colonizers developed an array of racist stereotypes, explanations, and rationalizations for their destruction of indigenous societies, enslavement of Africans, and other colonial exploitation. This array congealed in a broad *white racial framing*, a pervasive and increasingly dominant white worldview with racialized ideological, narrative, and other elements that emphasized the superior white 'race' and legitimated this extensive oppression and exploitation around the globe (Feagin, 2010b).

Racial and Ethnic Groups

Taking into account this history of asymmetrical racial relations and racial oppression, most social scientists define a *racial group* as a socially constructed group that people in- or outside that group have decided is important to single out as inferior or superior, typically on the basis of physical characteristics subjectively selected. For marking off racial groups, certain physical characteristics like skin color are often chosen, and other characteristics like eye or hair color usually are rejected, solely for social reasons. Similarly, an *ethnic group* is a group that is set apart by insiders or outsiders primarily on the basis of cultural or national-origin characteristics subjectively selected (Feagin and Feagin, 2011).

Racial and ethnic groups are not fixed groups or essential categories that endure forever, but rather are temporary human inventions that are constructed socially and usually are shaped in sociopolitical struggles at particular historical times and geographical places. Most important, they have significance and meaning only in relationship to group interaction.

Although the two types, racial and ethnic groups, can be distinguished on theoretical grounds, in the everyday operation of societies, racial and ethnic markers, identities, and oppressions usually are intertwined.

Conceptual Approaches to Racial Relations

Most conceptual approaches to racial (and ethnic) group relations can be classified roughly as (1) order-assimilation theories or (2) power-conflict theories. Order-assimilation theories tend to emphasize the gradual incorporation (assimilation) of immigrant groups into the dominant culture of a society and to give more attention to stability over time in intergroup relations. In contrast, power-conflict theories give central attention to the outcomes of racial (and ethnic) group contacts (immigrants and others) that result in oppression, labor exploitation, and genocide.

Assimilation Approaches

In Europe and the United States, much theorizing about racial and ethnic group relations has placed an emphasis on assimilation, on the more or less orderly adaptation of a migrating group, such as Italian or Russian immigrants to the United States in the early 1900s, to the ways of an established host group, such as the dominant white-Anglo-Protestant core culture of the United States then (and now). Related theories stress individual or group competition seen as resolving itself in the direction of eventual accommodation and assimilation (e.g., Banton, 1983). In most order-assimilation theorizing, relatively little attention has been paid to outcomes of intergroup contact taking the form of long-term or foundational racial oppression. One early US theorist, the influential University of Chicago sociologist Robert E. Park (1950), argued that intergroup relations generally move through the stages of a *race relations cycle* – contact, competition, accommodation, and eventual assimilation – that are more or less continuous and largely irreversible. Scholars in this assimilationist tradition typically have assumed that there is a long-term trend toward eventual adaptation of immigrant groups in Western societies to the dominant group and culture and that racial-ethnic conflicts will diminish with the eventual assimilation of incoming groups to the dominant core culture.

Giving primary attention to immigrants to the United States, influential sociologist Milton Gordon (1964) viewed the typical trend of such racial-ethnic group adaptation to be in the direction of immigrants giving up much of their home-country heritage for the preexisting and dominant white-Anglo-Protestant core culture. This group adaptation takes place in seven different and defined arenas of assimilation: cultural assimilation, structural (primary group) assimilation, marital assimilation, attitude-receptional assimilation (breakdown of prejudices), behavior-receptional assimilation (decline of discrimination), identificational assimilation, and civic assimilation. Mainstream assimilation theorists like the pioneering Gordon and subsequent researchers utilizing assimilation theory usually have had in mind as their main examples of racial-ethnic adaptation European immigrant groups migrating voluntarily to the United States or to various European nations. Over recent decades, this assimilation framework has persisted, in more nuanced form, as an influential mainstream perspective. Examples of the contemporary use of Gordon's typology can be seen in the research of sociologist Silvia Pedraza (1985) on Latino immigration to the United States and the research of sociologists Richard Alba and Victor Nee (2003) on white ethnic adaptation. Alba (2009) has drawn on the mainstream conceptualization of assimilation in critically assessing the contemporary loss of strong ethnic identities among white Americans. Richard Alba and Victor Nee (2003) have amplified this theoretical perspective by demonstrating reciprocity in the assimilation process – that is, how the cultures of immigrants have had an impact on the 'core' culture of society. Contemporary assimilation theory has become considerably more developed and nuanced than in earlier decades.

Still, mainstream US assimilation theorists have as a rule given relatively less attention to the adaptation of non-European groups to the US core culture than have power-conflict theorists. When they have, they have viewed non-Europeans as likely assimilating more or less like earlier white European immigrants. One prominent European researcher of US racial relations, Gunnar Myrdal (1964 [1944], vol. 2, p. 929), has argued that as a practical matter it is to the advantage of African Americans "as individuals and as a group to become assimilated into American culture, to acquire the traits held in esteem by the dominant white Americans." Even today, many order-assimilation analysts expect the importance of initial racial-ethnic stratification to decline as powerful universalistic forces, such as industrialization and urbanization, wipe out the vestiges of earlier particularistic value and racial-ethnic (including racist) coding systems in societies such as the United States.

Several social scientists (e.g., Mia Tuan, 1998) have used empirical field studies to examine certain problematical aspects of the assimilation perspective in regard to the contemporary experiences of immigrants of color and their immediate descendants. Their findings show that, even as Asian American immigrants and their children substantially acculturate to the Anglo-American core culture, most retain a strong racialized identity – substantially because they regularly suffer discrimination from whites who constantly impose on them the racially stereotyped identity of undesirable 'alien' and 'foreigner.' Contrary to the perspective of Gordon and some recent mainstream assimilation thinkers, most Asian Americans, in spite of significant cultural and socioeconomic assimilation, remain racialized and thus a substantial distance from being fully accepted and assimilated into white middle-class society.

Power-Conflict Approaches

Generally speaking, mainstream assimilation theorists are most concerned with cultural (such as language) or primary-group network (such as intermarriage) features of the adaptation of migrating groups to a host society, whereas power-conflict theorists are most concerned with racial-ethnic oppression, exploitation, and subordination that affect incoming and other groups in society. An early US advocate of this perspective, Oliver C. Cox (1948), emphasized the role of the capitalist class

in creating racial conflict by exploiting the labor of groups like African Americans and propagating racist ideologies to divide the working class in Western societies such as the United States. Providing much evidence, scholars in this power-conflict tradition have shown that early racial (e.g., white-on-black) stratification largely grew out of the global and other territorial expansion of profit-oriented capitalism and has continued to be reinforced and maintained by still-extant capitalism and associated imperialism.

Some scholars have drawn on theoretical discussions of external colonialism and developed the concept of *internal colonialism* to describe what happens to many non-European groups coming into and integrated into Western societies. An emphasis on great power inequalities between whites and people of color is generally at the heart of this model. Thus, people of color, such as Native Americans and African Americans, were brought into the sphere of expanding capitalistic system of North America by force. Subsequent group adaptation was characterized by extensive dominant-group coercion and oppression of these racially subordinated groups, as well as by significant group resistance by the latter. Racial stratification thus has a firm material base, an underpinning rooted in a specific political–economic histories. Internal-colonialism theorists are not concerned primarily with white immigrant groups but rather with the persistence of systemic oppression and the asymmetrical control processes that maintain white dominance over various groups of color in a society like the United States (Blauner, 1972).

Power-conflict analysts look at the immigration of non-European peoples as involving much more than continuous assimilation. John Rex (1973) has analyzed the immigration of such groups from the former European colonies to the metropolitan cities of numerous colonizing countries. In the latter countries, most of these colonial immigrants of color historically have gotten inferior and marginal jobs and often have suffered higher unemployment – thereby typically becoming structurally distinct from the native-born, white working and middle classes and, thus, a low-ranking social group often viewed as alien or foreign.

Generally, power-conflict analysts emphasize the direct and continuing impact of structural racial barriers on people of color in countries around the globe. In the 1980s and 1990s, innovative sociologists Michael Omi and Howard Winant (1994) developed an important theory of 'racial formation.' Racial formation is the "sociohistorical process by which racial categories are created, inhabited, transformed, and destroyed" in societies like the United States (Omi and Winant, 1994, p. 55). Critically reviewing prior theorizing – especially that of assimilation (ethnicity) and Marxist theorists – that avoided or downplayed racial oppression issues in favor of accents on ethnicity or class, Omi and Winant have emphasized the continuing significance of racial formations in the United States over the generations. From their influential perspective, asymmetrical racial relationships are substantially defined by state action, such as that defining who is 'black' and 'white' (the infamous 'one drop of blood' US rule) or that restricting immigration to the United States from Asian and Latin American countries on the basis of racist reasoning. Numerous social science and humanities scholars have made significant use of this racial formation theory in theorizing about issues, such as struggles among whites and Mexican Americans, racism and popular culture, and interpreting the societal construction of race (see Gomez, 2002; Brock, 2009).

Other power-conflict analysts (see Feagin and Elias, 2012) have demonstrated that the racial formation approach of Omi and Winant does not go far enough in probing empirically and theorizing thoroughly the foundational and systemic reality of racial oppression in white-settler societies like the United States. The concept of *systemic racism* (also termed *institutional racism*) emphasizes the importance of these determining patterns of racial oppression that are threaded throughout a society's everyday operations and institutions – and well beyond the state institutions. From its major development in the seventeenth century to the twenty-first century, white-imposed racism has been about much more than whites'racist attitudes and biases, for it has long encompassed a complex array of racially inegalitarian economic, political, and other social relationships developed and sustained over many generations and embedded in all major institutions in the United States and other Eurocentric societies (Du Bois, 1965 [1946]; Feagin, 2010a).

In the US case, from the 1600s to the present, the dominant white group – especially, the white male elite – has created and maintained the hierarchical patterns of racial oppression. They have created and perpetuated the oppressive practices that unjustly enrich the dominant white group and unjustly impoverish groups of color. The long history of white oppression in the US case has been well documented by an array of social scientists (Frederickson, 2008/1971, 1987; Singh, 2005; Feagin, 2010a). In racist systems, such as that of the United States, most whites become privileged stakeholders in a hierarchical structure of opportunities, resources, wealth, and power linked to a long history of racial exploitation and oppression.

Among others, Joe Feagin (2010a; see also Feagin and Feagin, 2011) has argued that the concept of *systemic racism* encompasses both the creation and sustained maintenance of substantial white privilege and power in society and the construction of a broad *white racial frame* to explain and rationalize that unjustly gained privilege and power. Individuals, whether they are the perpetrators or recipients of racial oppression, are caught in a complex web of alienating individual and group relationships. Systemic racism divides human beings and severely impedes the development of a common consciousness. At the macro level, large-scale institutions routinely perpetuate the subordination of certain racial groups to yet other racial groups. In turn, these racially inegalitarian institutions are maintained by recurring discriminatory practices of dominant-group individuals at the micro level of everyday interaction. Individual acts of discrimination activate, on a recurring basis, whites' major power-and-privilege position, a point underscored by, among others, the pioneering European scholar of institutional racism, Philomena Essed (1991).

In some theorizing about contemporary racial conflict and inequality, there is an emphasis on the growing importance of class, defined in the Weberian sense of socioeconomic status. Some of these analysts argue that systemic racism is of declining importance in Western societies like the United States and increasingly is consigned to societal fringes, whereas socioeconomic (class) divisions are increasing (Wilson, 1978). Yet research evidence suggests that such a conclusion is

premature. Critics (e.g., Omi and Winant, 1994; Feagin, 2010a) of this view of the 'declining significance of race' have shown that, for the United States at least, race cannot be reduced to socioeconomic status and divisions, but rather it remains an autonomous and continuing field of much intergroup conflict, political organization, and ideological meanings.

Some contemporary theorizing about racial and ethnic relations, especially 'segmented assimilation' theory, draws heavily on the mainstream assimilation tradition, yet also makes use of power-conflict ideas. Researchers like Alejandro Portes (1995) have argued that societal outcomes of immigrant adaptation vary greatly, with groups of color like Mexican Americans substantially confined to the lower rungs of US society's economic ladder in later generations, even as other groups such as early twentieth-century European immigrants have experienced over generations much faster socioeconomic mobility. Researchers (Portes, 1995) have found that the second-generation children of relatively recent Mexican immigrants, unlike children of European immigrants, continue to face racial-ethnic discrimination and related difficult economic circumstances, including disproportionate placement in low-paying jobs and inadequate housing. These researchers underscore the significant problems associated with traditional immigrant-assimilation theories when they are applied to immigrants of color and have insisted on spelling out who is being assimilated and under what circumstances.

Continuing Racial Oppression: The US Case

In the twenty-first century, people of African descent appear to be the globe's largest racially oppressed group; they are now resident in a number of countries as a result of the overseas slave trade carried out by Europeans centuries ago. One of the major groups in this large-scale African diaspora includes the residents in the United States, where much research evidence remains of continuing white-on-black discrimination and other racial oppression.

Recent field studies and opinion surveys show that among white Americans, racist attitudes and other racial framing remain widespread. Psychologists recently have given implicit racial attitude tests online to thousands of white Americans. The overwhelming majority quickly associate black faces with negative words and traits, yet they have more difficulty in quickly associating black faces with pleasant words and positive traits than they do for white faces. In these and other research tests, most whites of various educations and occupations have revealed a strong antiblack and a prowhite bias (for a summary, see Feagin, 2010a, pp. 102–103). In addition, recent surveys of African Americans have found that a substantial majority report that they as a group face significant discrimination from whites in local housing, employment, restaurants, and other institutional areas (Feagin, 2010a, p. 120). One focus-group study (Nuru-Jeter et al., 2009) involving black women found that they reported numerous instances of discrimination in schools, housing, shopping, and health care institutions; additionally, they stressed how vigilant they must be in countering the everyday racism faced by themselves and their families. Numerous studies demonstrate that African Americans continue to face significant discrimination from police officers doing racial profiling and from real estate agents and landlords who engage in antiblack housing discrimination (Smith, 2006).

In the United States, as in numerous other white-controlled countries, whites also direct much racist framing, hostility, and discrimination at other groups of color. Numerous research studies have shown that many Asian Americans are moving into the mainstream of the US economy and suburban neighborhoods, yet as they do so, they still encounter much racial discrimination at the hands of whites. Blue-collar and white-collar workers, including administrators and professionals in historically white institutions, report ingrained patterns of anti-Asian discrimination (Cheng, 1997; Feagin, 2010a, pp. 244–245). Similarly, Latino Americans report much continuing discrimination in employment and housing. Political discrimination targets Latino and Asian Americans. Over recent decades, voters in the state of California, especially white voters, have supported ballot propositions designed to abolish government services for Latino and Asian immigrants and eliminate antidiscrimination (e.g., affirmative action) and bilingual programs. White hostility to Spanish-speaking Americans of color persists, such as in the widespread mocking of the Spanish language and other aspects of Latino culture in the United States (Feagin, 2010a, pp. 221, 240–247).

Racism in Europe: The Case of France

The United States is not the only Western nation pervaded by a white racial framing of society and thus of racist relations. The reality of racial oppression can be seen in the growth of neo-Nazi groups and the often-associated outbreak of hate crimes in many European countries since the 1980s, as well as in routine discrimination in housing and employment in those European countries. For example, in France, immigrants from Algeria and other African countries often face racist framing, hostility, and discrimination much like that of the United States. France imposed colonial rule on Algeria in the nineteenth century; later, beginning in the 1960s, large numbers of Algerian immigrants migrated to France. Defining these and other African immigrant groups as undesirable, many French whites have publicly alleged the lack of assimilation by African immigrants into (white) French culture as the major issue. Yet, these whites typically play down or ignore the way in which such societal realities as housing separation and other social segregation result from institutionalized, race-linked discrimination by whites against French people of African descent. In France racist–right political groups like the French National Front – with its strong white racial framing, anti-immigrant, and anti-multiculturalism agendas – have grown in social and political influence in recent years. In the 2012 election, the head of the National Front ran as a presidential candidate and got millions of votes. The national government in France periodically responded to white voters' pressures with its own racialized anti-immigrant framing and repressive attacks on African immigrants and their French descendants (Batur-VanderLippe, 2011; Hollinger, 2012).

For numerous European countries, overseas colonialism in areas like Africa involved the use of organized violence to exploit the resources of the colonies there and to oppress their indigenous peoples – practices often legitimated with a strong white-racist framing and Eurocentric ideologies (Du Bois, 1965 [1946]; Batur-VanderLippe, 2011). More recently, the descendants of the formerly colonized often face racial oppression in the colonizers' home countries. In a number of European countries, the legacy of colonialism can be seen graphically in the often-violent expressions of racialized hatred for the identity and culture of African, Asian, Middle Eastern, or West Indian immigrants and their descendants in Europe.

Still, there are some differences between Europe's racist patterns and those of the United States. One example can be seen in the dramatic increase in white supremacist and other hate-oriented websites on the Internet. The number of these websites is estimated to be at least 5000, with some estimates being much higher. Although European countries do have a serious problem with racist and other hate websites and their mostly white followers, a majority of the major racist and other hate-speech websites are based in the United States – in part because of the way that judges and politicians in the United States interpret the US Constitution's first amendment to protect most hate speech. In contrast, many European countries, including Italy, Austria, England, France, Germany, and the Netherlands, have important laws that significantly restrict white supremacist and other hate speech both on the Internet and in other societal settings.

Racism in Former European Empires: The South African Case

In many ways South Africa is a major symbol of racist relations as they developed between European and non-European peoples in the ever-spreading European empires from the sixteenth to the nineteenth centuries. In the South African case, two colonizing powers, Great Britain and Holland, invaded the lands of the indigenous African peoples, and their white descendants became the economically and politically dominant group in the country. In the first decade of the twentieth century, a new country, called the Union of South Africa, was formed, combining white residents of British and Dutch origin as the ruling group over several black African groups. Black Africans gradually were forced into a system of comprehensive racial segregation (called apartheid) where the relations between the white and black groups, as well as between these groups and middle groups like the Asians and the 'coloreds' (those of mixed racial backgrounds), were determined by an asymmetrical racial hierarchy and an extensive system of racial segregation laws. Over time, the racial apartheid system came to encompass most aspects of the relations between white residents and residents of color, including relationships of great racial oppression in the major institutional areas of politics, employment, education, and housing (Batur-VanderLippe, 2011; Feagin and Feagin, 2011).

As in the case of African Americans, this comprehensive system of racial oppression especially targeted *black* South Africans. As a result, apartheid generated much black resistance in the form of major organizations like the African National Congress (ANC). The ANC, working with other antiapartheid groups, engaged in collective protests and eventually forced an end to white-imposed apartheid, thereby bringing new hope for improved living conditions for the oppressed black majority. Racial relations in numerous spheres dramatically changed. In the mid-1990s, the Republic of South Africa (the country's name changed in the 1960s) moved from white to black political control and began to change its traditional patterns of political, economic, and social apartheid. This societal change has so far marked only a significant beginning, for the important political changes have not yet ended extensive economic domination by whites, and the country still ranks very high among the world's countries in unemployment and socioeconomic inequality along racial lines. Racially discriminatory practices – blatant, subtle, and indirect – still are found in numerous areas, including employment, housing, and education. Educational and other socioeconomic mobility opportunities, although much better than in the past, are limited severely by the unjust impoverishment of most black African families over generations of racial apartheid imposed by whites and its continuing impact on the assets and resources available to black families to the present day. Attempts at remedial and reparatory action by the black-led government have helped to create a black middle class, but they have not yet provided much sustained improvement in socioeconomic conditions for the black working-class majority (Batur-VanderLippe, 2011; Feagin and Feagin, 2011).

These late-twentieth-century events in South Africa have helped to link black African-origin peoples around the globe in a common struggle against the descendants of European colonists, who have long maintained economic or political control in numerous countries where people of color are the numerical majority. Struggles against systemic racism in one country often inspire or inform struggles in other countries. Since the early 1900s, for example, black American efforts for liberation from white racism, including recurring black civil rights movements, have provided inspiration and assistance for struggles of people of color in South Africa and other countries with significant oppressed populations (e.g., Brazil). In a similar fashion, the successes of black Africans in South Africa in bringing down political and other apartheids have encouraged African-origin peoples in the United States and other countries in the Americas in their struggles against racial framing and racial discrimination. Indeed, African Americans have long drawn on the history, spirituality, and symbolism of Africa as part of their individual and group strategies for countering and coping with a white-dominated and racialized US society. These cross-national examples again suggest how racial relations and racist histories in one country have been set within a larger global racial context. This has been true for centuries now (Feagin and Feagin, 2011; Batur-VanderLippe, 2011).

The Future of the Global Racial Order

Over several centuries, the global expansion of capitalism by European entrepreneurs, colonists, and missionaries – European colonialism and imperialism – frequently generated an extensive system of white-racist oppression and

framing, one with a global scope. Eventually, in the early twentieth century, a substantial majority of this planet's people of color were dominated in one way or another by people of European descent (see Batur-VanderLippe, 2011). Yet this oppression eventually generated large-scale resistance and periodically substantial change.

In many countries around the globe, recurring challenges to white racial domination and its discriminatory consequences are arising not only from human-rights organizations' efforts but also from important demographic and sociopolitical changes. Europeans and European Americans are a decreasing fifth of the world's population and a decreasing proportion of the US population. In the second decade of the twenty-first century, US whites are a statistical minority in many large cities and in the states of New Mexico, Hawaii, California, and Texas. Demographic projections indicate that no later than the year 2050, white Americans will be a statistical minority of the US population, for the first time since the country's beginning in the 1790s. According to a 2011 US Census Bureau's official count, the white non-Hispanic population percentage had declined to just 63%, and the white proportion of babies born had dropped for the first time to just under 50%.

As whites become the statistical minority in the United States and in the many national and international organizations they once dominated, traditional patterns of white-dominant racial relations will be under greater pressure to change. The demographic changes have significant political, economic, and other social implications. For the US case, by the 2040s, the majority of the labor force will very likely not be white, and the population and labor force will be older. This likely will give Americans of color yet more political and economic clout. Political–economic tensions may well increase between a mostly white retired population and the majority of the nonwhite working population. In the United States and other Western countries, white politicians intensely opposed to legal immigration by non-Europeans and to major remedial programs for racial discrimination likely will not be elected when much larger proportions of political constituencies become voters of color. As these constituencies change away from white dominance, it seems probable that juries and justice systems, education systems, government policy-making arenas, and other societal institutions also will change in the direction of more influence and power for citizens of color.

Around the globe, the relations of colonialism and systemic racism are slowly but dramatically changing. The deep-lying contradictions of the global racial order were set into motion by the colonial and imperialistic ventures of numerous European nations. This European colonialism generated sociopolitical structures that have long embedded the practices, ideologies, and institutions of racist subordination in numerous countries. In the twenty-first century, international relations, global markets, the global mainstream media, and multinational corporations are all racialized, with white European perspectives and white or white-oriented executives usually in control. Half a millennium of European-dominated national and international institutions is slowly coming to an end. As the twenty-first century develops further, asymmetrical racial relations and racial hierarchies in Europe, the United States, and other parts of the globe are likely to change substantially. Many once racially oppressed groups probably will move farther out from under the racialized dominance of Europeans and European Americans.

Not surprisingly, over the past few decades, strong anti-racism movements have arisen in South Africa, Brazil, the United States, and other countries with colonial histories. The possibility of a global democratic order substantially rid of the oppressive relations of white-imposed racism remains only a dream, but the US civil rights movements and the South African political revolution, among other racialized global struggles, demonstrate that it is still a powerful dream for a great many people around the globe.

Abstract

Initially seen by historians as a theory of difference, racism is now usually seen as an ideology with an integral relationship to domination or exclusion. The most conspicuous forms of modern racism – white supremacy and antisemitism – have been studied separately. A general or comparative history could be based on a definition of racism as an ideology sanctioning the domination or exclusion of one ethnic group by another on the basis of difference believed to be hereditary and unalterable. Racism can, thus, be distinguished from xenophobia and religious intolerance. It emerged in the late medieval and early modern periods in conceptions of Jewishness as ancestry rather than belief and of blackness as a curse condemning Africans to servitude. The scientific revolution and the Enlightenment provided foundations for naturalistic racism. The struggle over slavery and the accelerated expansion of Europe into Africa and Asia brought color-coded racism to full consciousness in the nineteenth century. European antisemitic racism emerged in the context of modernity and the emancipation of the Jews. Racism climaxed during the twentieth century in the segregation of blacks in the American South and in South Africa, and in the genocidal assault on European Jewry.

Initially viewed by historians as a theory of difference, racism is now usually seen as an ideology with an integral relationship to domination or exclusion. The most conspicuous forms of modern racism – white supremacy and antisemitism – have been studied separately. A general or comparative history could be based on a definition of racism as an ideology sanctioning the domination or exclusion of one ethnic group by another on the basis of difference believed to be hereditary and unalterable. Racism can, thus, be distinguished from xenophobia and religious intolerance. It emerges in the late medieval and early modern periods in conceptions of Jewishness as ancestry rather than belief and of blackness as a curse condemning Africans to servitude. The scientific revolution and the Enlightenment provided foundations for naturalistic racism. The struggle over slavery and the accelerated expansion of Europe into Africa and Asia brought color-coded racism to full consciousness in the nineteenth century. European antisemitic racism emerged in the context of modernity and the emancipation of the Jews. Racism climaxed during the twentieth century in the segregation of blacks in the American South and in South Africa and in the genocidal assault on European Jewry.

In common usage the term racism is often employed in a loose and unreflective way to describe the hostile or negative feelings of one ethnic group or historical collectivity toward another and the actions resulting from such attitudes. But historians and social scientists normally require a more precise and limited definition, although they may disagree on what it should be. It is useful, therefore, to review the historiographic discourse on the meaning of racism before attempting a brief survey of what contemporary historians might accept as its principal manifestations.

Historiography of Racism

The term racism was coined in the 1930s mainly in reference to the theories on which the Nazis based their persecution of the Jews. The first historian to focus directly on the subject was Barzun. His book *Race: A Study in Superstition* (originally published in 1937 and reprinted in 1965) set two important precedents for most future historians of racism: it presumed that claims of the innate inferiority of one 'race' to another were false or at least unproven, and its main concern was with the history of ideas rather than with the social and political applications of prejudiced beliefs and attitudes. Barzun's concern with the intellectual origins of Nazi antisemitism was shared by the many scholars who wrote on the subject after World War II in response to what the Holocaust had revealed about the horrifying consequences of racist ideas. A notable example was Poliakov's *Le Myth Aryen*, translated into English as *The Aryan Myth* (1974). But disagreements developed on whether biological racism was continuous with earlier antisemitic attitudes that were, ostensibly at least, based on religion or whether it was a radical new departure, a *sine qua non* for something like the Holocaust.

In the immediate postwar decades, the term racism was also applied with increasing frequency to the relationships between whites or Europeans and people of color, especially Africans or those of African descent, in colonial, postcolonial, and former slave societies. The rising concern with black-white relations in the US, South Africa, and (to a somewhat lesser extent) in Great Britain, beginning in the 1950s and early 1960s, gave rise to an enormous literature on the origins and development of white supremacy as an ideology. Historians of ideas did most of the early work, but gradually the emphasis shifted somewhat from the racist ideas themselves to the patterns or racial discrimination and domination for which they served as a rationale. Many historians of black-white relations used the term casually and without reflecting on its exact meaning. Most imprecisely, it could mean anything that whites did or thought that worked to the disadvantage of blacks.

There have been relatively few attempts to write general histories of racism, which encompass both the antisemitic and color-coded varieties. For the most part, the two historiographies have not addressed each other, and the definitions

employed have sometimes been incompatible. Some historians of antisemitic racism have found the term applicable only if the aim was the elimination of the stigmatized group. Some historians of white supremacy, on the contrary, would limit the term to ideologies associated with patterns of domination or hierarchical differentiation. The first attempt at a comprehensive history of American racism, Gossett's *Race: The History of an Idea in America* (1963) traced consciousness of race to the ancient world. Its treatment of specifically American manifestations cast its net quite wide to include representation and treatment of American Indians and immigrants from southern and eastern Europe, including Jews, as well as blacks. But most subsequent work on the history of American racism has been group-specific and has concentrated most heavily on attitudes toward African Americans. Mosse's general history of European racism, on the other hand, pays most of its attention to the growth of antisemitism between the Enlightenment and the Holocaust (Mosse, 1978). But there appear to be only two significant attempts to cover Western attitudes toward race comprehensively: Hannaford's *Race: The History of an Idea in the West* (1996) and Geiss' *Geschichte des Rassismus* (1988). Hannaford's study, as its title indicates, is strictly an intellectual history and considers race as a concept more than racism as an ideology. It argues strenuously that no clear concept of race existed before the seventeenth century, thus raising the issue of whether anything that existed before the invention of race in the modern sense can be legitimately labeled racism. Geiss, on the contrary, sees racism as anticipated in most respects by the ethnocentrism or xenophobia that developed in the ancient world, as reflected, for example, in the Old Testament.

Toward a Definition of Racism for Historical Purposes

Somewhere between the view that race is a peculiar modern idea without much historical precedent and the notion that it is simply an extension of the ancient phenomena of ethnocentrism and xenophobia may lie a working definition that is neither too broad for historical specificity or too narrow to cover more than the limited span of Western history during which a racism based on scientific theories of human variation was widely accepted. If racism is defined as an ideology rather than as a theory, links can be established between belief and practice that the history of ideas may obscure. But ideologies have content, and it is necessary to distinguish racist ideologies from other belief systems that emphasize human differences and can be used as rationalizations of inequality. The classic sociological distinction between racism and ethnocentrism is helpful, but not perhaps in the usual sense, in which the key variable is whether differences are described in cultural or physical terms. It is actually quite difficult in specific historical cases to say whether appearance or 'culture' is the source of the salient differences, because culture can be reified and essentialized to the point where it has the same deterministic effect as skin color. But it would stretch the concept of racism much too far to make it cover the pride and loyalty that may result from ethnic identity. Such groupcenteredness may engender prejudice and discrimination against those outside the group, but two additional elements would seem to be required before the categorization of racism is justified. One is a belief that the differences between the ethnic groups involved are permanent and ineradicable. If conversion or assimilation is genuinely on offer, we have religious or cultural intolerance but not racism. The second is the social side of the ideology – its linkage to patterns of domination or exclusion. To attempt a short formulation, we might say that racism exists when one ethnic group or historical collectivity dominates, excludes, or seeks to eliminate another on the basis of differences that it believes are hereditary and unalterable.

The Emergence of Racism

Historians who can accept this middle-of-the-road definition can agree with the scholars who have examined conceptions of human diversity in classical antiquity and the early Middle Ages without finding clear evidence of color prejudice or racism. Neither the classical conception that one becomes civilized through being able to engage in politics nor the Christian belief that everyone regardless of color or ancestry is a potential convert with a soul to be saved could readily sustain a racist view of the world. The period between the fourteenth and the seventeenth centuries is much more problematic. The literal demonization of the Jews in the late Middle Ages, the belief that they were in league with the devil and plotting the destruction of Christianity, could lead unsophisticated folk to believe that they were outside the bounds of humanity, even though church authorities persisted in advocating their conversion. Folk antisemitism resulted in massacres and expulsions of Jews in virtually every country in Western Europe. A degree of elite or official sanction for such attitudes came in sixteenth century Spain when Jews who had converted to Christianity and their descendants became the victims of a pattern of discrimination and exclusion. When purity of blood, or *limpieza de sangre*, became a qualification for certain offices and honors it signified that what people could accomplish or achieve no longer depended on what they did but on who they were. Precedents for the notion that blood will tell could be found in the inheritability of royal or noble status but the designation of an entire ethnic group as incapable of a reliable conversion to Christianity constituted, at the very least, a transitional stage between religious bigotry and biological racism.

The period of the Renaissance and Reformation was also the time when Europeans were coming into increasing contact with people of darker pigmentation in Africa, Asia, and the Americas and were making judgments about them as they traded with them, fought with them over territory, or enslaved them. A belief that all these non-Europeans were children of God with souls that missionaries could save did not prevent a brutal expropriation of their land and labor, but it did inhibit the articulation of a racial justification for how they were being treated. When Africans were carried by force to the New World to labor on plantations, slave traders and slave owners sometimes invoked an obscure passage in the book of Genesis to explain the color of their human property. Ham had committed a sin against his father Noah that resulted in a divine curse on his descendents to be 'servants unto servants.' When Africans were enslaved, first by Arabs, and then by Europeans, it became convenient to believe that the

punishment of God had included a blackening of the skin. But the passage had other possible meanings, and no orthodox religious authorities ever endorsed the interpretation of the curse popular among slaveholders, because they feared that it would impede conversion of blacks to Christianity. The standard and official justification for enslaving Africans was that they were heathens and that enslavement made heaven accessible to them.

An implicit racism became evident, however, when converted slaves were kept in bondage, not because they were actual heathens but because they had heathen ancestry. As with the doctrine of purity of blood in Spain, descent rather than performance became the basis for determining the qualifications for membership in a community that was still theoretically based on a shared Christian faith. Beginning in the late seventeenth century laws were passed in English North America forbidding marriage between whites and blacks and discriminating against the mixed offspring of informal liaisons. Without clearly saying so, such laws implied that blacks were unalterably alien and inferior.

The Rise of Modern Racism

A modern naturalistic form of racism could not be articulated fully until the Enlightenment. A secular or scientific theory of race required a new way of looking at human diversity, one that moved the subject away from the Bible, with its insistence on the essential unity and homogeneity of the human race and its collective elevation above the animal kingdom. Eighteenth-century ethnologists began to think of human beings as part of the natural world and subdivided them into three to five races, usually considered as varieties or subspecies. Most eighteenth-century ethnological theorists believed that whiteness was the original color of humanity and that blackness or brownness resulted from a process of degeneration caused by climate and conditions of life. Although the white or Caucasian race was generally considered more beautiful and civilized than the Mongolian and especially the Negro, the belief that human beings constituted a single species with a common origin remained dominant. In the late eighteenth and early nineteenth centuries, however, an increasing number of ethnologists asserted that the races were separately created and constituted distinct species. As debates over the morality of slavery and the slave trade erupted in Western Europe and the US in the wake of democratic revolutions and the rise of humanitarian movements, some of the most militant defenders of black bondage adopted these polygenetic arguments as a justification for enslaving Africans and holding them in permanent servitude. But the fact that polygenesis seemed to conflict with scripture limited the usage of this extreme version of scientific racism. Many defenders of slavery in the American South, where evangelical religion enforced biblical literalism, reverted to the Curse on Ham or made the degeneracy hypothesis of Enlightenment ethnology into an argument for the permanent or irreversible divergence of the races from their common origin.

The nineteenth century was an age of emancipation, nationalism, and imperialism – all of which contributed to the growth and intensification of ideological racism in Europe and in the US. Although the emancipation of blacks from slavery and Jews from the ghettoes, which seemed a logical consequence of the democratic revolutions of the late eighteenth century, received most of its support from religious or secular believers in an essential human equality, the consequences of these reforms was to intensify rather than diminish racism. Race relations became less paternalistic and more competitive. Poor or working class whites in the US, for example, feared competition with emancipated blacks for work, land, and social status. Middle-class (especially lower middle class) Germans viewed the increasing involvement of Jews in finance, commerce, the professions, journalism, and the arts during the late nineteenth century as a potential threat to their own economic security, social status, and traditional values. Of course, it was the legacy of inherited stereotypes about 'the Other,' in addition to the immediate economic and social circumstances, that gave edge and intensity to these feelings of insecurity and hostility. The idiom of Darwinism, with its emphasis on 'the struggle for existence' and concern for 'the survival of the fittest' was conducive to the development of a new and more credible scientific racism in an era that increasingly viewed race relations as an arena for conflict rather than as a stable hierarchy.

The growth of nationalism, especially romantic cultural nationalism, encouraged the growth of a more mystical variant of racist thought. When it could be assumed that one had to be of German ancestry to participate in the German *Volkgeist*, Jews could be discriminated against or excluded just as effectively as if their deficiencies were clearly defined as genetic or biological. For most of the nineteenth century the question of whether German Jews could or should be converted to Christianity was an open one. Beginning in the late 1870s and early 1880s, however, the coiners of the term 'antisemitism' made explicit what some cultural nationalists had previously implied – that to be Jewish was not simply to adhere to a set of religious beliefs or cultural practices but meant belonging to a race that was the antithesis of the race to which true Germans belonged. The latter was variously designated as Teutonic, Aryan, Nordic, or simply Germanic. In Great Britain and the US romantic nationalism took the form of a veneration for Anglo-Saxon ancestors and legacies that could turn racist, as it did for a time in the US, when confronted with large-scale immigration from eastern and southern Europe. In France, an ethnocentric cultural nationalism fed the fury against the Jews that surfaced in the Dreyfus affair at the turn of century. It did not triumph against the universalistic civic nationalism inherited from the revolutionary past, but it did make antisemitic racism a strain of right-wing French thought that would resurface during the 1930s and especially under the German occupation.

The climax of Western imperialism in the late nineteenth century 'scramble for Africa' and parts of Asia and the Pacific represented an assertion of the competitive ethnic nationalism that existed among European nations (and which, as a result of the Spanish-American War came to include the US). A belief that different races, subraces, or racial mixtures inhabited each nation led some, especially the Germans and the English, to suppose that the quality of each nation's racial stock was being tested for its fitness. But imperialism also required the massive subjugation and colonial domination of non-European populations. An ideology proclaiming that whites were superior to

'lesser breeds' and responsible for ruling over them and tutoring them in the rudiments of civilization was a prime rationale for this new burst of European expansionism, even if it was not a cause of it. The relation of racism to imperialism is more problematic than one might suppose, however, because the most consistent and extreme racists were often anti-imperialists. They believed that nothing useful could be done with people whose inferiority was so profound and permanent that they were incapable of being civilized. For them the taming or domestication of such savages was not worth the trouble. Within colonies that attracted substantial numbers of European settlers, such as French Algeria or some of the British colonies of South and East Africa, a more extreme and explicit racism than the one usually professed by government officials or missionaries could be found in the discourse of white colonists about their 'native' servants or farm laborers.

The Climax: Racism in the Twentieth Century

The climax of the history of racism came in the twentieth century in the rise and fall of what might be called overtly racist regimes. In the American South, the passage of racial segregation laws and restrictions on black voting rights reduced African Americans to lower caste status, despite the Constitutional Amendments that had made them equal citizens. Extreme racist propaganda, which represented black males as ravening beasts lusting after white women, served to rationalize the practice of lynching. These extralegal executions increasingly were reserved for blacks accused of offenses against the color line, and they became more brutal and sadistic as time went on; by the early twentieth century victims were likely to be tortured to death rather than simply being killed. A key feature of the racist regime maintained by state law in the South was a fear of sexual contamination through rape or intermarriage, which led to efforts to prevent the conjugal union of whites with those with any known or discernable African ancestry. The effort to guarantee 'race purity' in the American South anticipated aspects of the official Nazi persecution of Jews in the 1930s. The Nuremberg laws of 1935 prohibited intermarriage or sexual relations between Jews and Gentiles, and the propaganda surrounding the legislation emphasized the sexual threat that predatory Jewish males presented to German womanhood and the purity of German blood. Racist ideology was eventually of course carried to a more extreme point in Nazi Germany than in the American South of the Jim Crow era. Individual blacks had been hanged or burned to death by the lynch mobs to serve as examples to insure that the mass of southern African Americans would scrupulously respect the color line. But it took Hitler and the Nazis to attempt the extermination of an entire ethnic group on the basis of a racist ideology.

Hitler, it has been said, gave racism a bad name. The moral revulsion of people throughout the world against what the Nazis did, reinforced by scientific studies undermining racist genetics (or eugenics), served to discredit the scientific racism that had been respectable and influential in the US and Europe before World War II. But explicit racism also came under devastating attack from the new nations resulting from the decolonization of Africa and Asia and their representatives in the United Nations. The Civil Rights movement in the US, which succeeded in outlawing legalized racial segregation and discrimination in the 1960s, was the beneficiary of revulsion against the Holocaust as a logical outcome of racism. But it also drew crucial support from the growing sense that national interests were threatened when blacks in the US were mistreated and abused. In the competition with the Soviet Union for 'the hearts and minds' of independent Africans and Asians, Jim Crow and the ideology that sustained it became a national embarrassment with possible strategic consequences.

The one overtly racist regime that survived World War II and the Cold War was the South African, which did not in fact come to fruition until the advent of Apartheid in 1948. The laws passed banning all marriage and sexual relations between different 'population groups' and requiring separate residential areas for people of mixed race ('Coloreds'), as well as for Africans, signified the same obsession with 'race purity' that characterized the other racist regimes. However, the climate of world opinion in the wake of the Holocaust induced apologists for apartheid to avoid straightforward biological racism and rest their case for 'separate development' mainly on cultural rather than physical differences. The extent to which Afrikaner nationalism was inspired by nineteenth-century European cultural nationalism also contributed to this avoidance of a pseudoscientific rationale. No better example can be found of how a 'cultural essentialism' based on nationality can do the work of a racism based squarely on skin color or other physical characteristics. The South African government also tried to accommodate itself to the age of decolonization. It offered a dubious independence to the overcrowded 'homelands,' from which African migrants went forth to work for limited periods in the mines and factories of the nine-tenths of the country reserved for a white minority that constituted less than a sixth of the total population.

The End of Racism?

The defeat of Nazi Germany, the desegregation of the American South in the 1960s, and the establishment of majority rule in South Africa suggest that regimes based on biological racism or its cultural essentialist equivalent are a thing of the past. But racism does not require the full and explicit support of the state and the law. Nor does it require an ideology centered on the concept of biological inequality. Discrimination by institutions and individuals against those perceived as racially different can long persist and even flourish under the illusion of nonracism, as historians of Brazil have discovered recently. The use of allegedly deep-seated cultural differences as a justification for hostility and discrimination against newcomers from the Third World in several European countries has led to allegations of a new 'cultural racism.' Similarly, those sympathetic to the plight of poor African Americans and Latinos in the US have described as 'racist' the view of some whites that many denizens of the ghettos and barrios can be written off as incurably infected by cultural pathologies. From the historian's perspective such recent examples of cultural determinism are not in fact unprecedented. They rather represent a reversion to the way that the differences between ethnoracial groups could be made to seem indelible and unbridgeable before the articulation of a scientific or naturalistic conception of race in the eighteenth century.

Abstract

The sociology of racism is the study of the relationship between racism, racial discrimination, and racial inequality. While past scholarship emphasized overtly racist attitudes and policies, contemporary sociology considers racism as individual- and group-level processes and structures that are implicated in the reproduction of racial inequality in diffuse and often subtle ways. Although some social scientists decry this conceptual broadening, most agree that a multivalent approach to the study of racism is at once socially important and analytically useful for understanding the persistence of racial inequality in a purportedly 'postracial' society.

At root, racism is "an ideology of racial domination" (Wilson, 1999: p. 14) in which the presumed biological or cultural superiority of one or more racial groups is used to justify or prescribe the inferior treatment or social position(s) of other racial groups. Through the process of racialization (see Section Racism as a Social Process), perceived patterns of physical difference – such as skin color or eye shape – are used to differentiate groups of people, thereby constituting them as 'races'; racialization becomes racism when it involves the hierarchical and socially consequential valuation of racial groups.

Racism is analytically distinct from racial discrimination and racial inequality. Racial discrimination concerns the unequal treatment of races, whereas racial inequality concerns unequal outcomes (in income, education, health, etc.). While racism is often implicated in both processes, contemporary racial inequalities and forms of discrimination are not always the immediate result of contemporary racism (Pager and Shepherd, 2008). The sociology of racism investigates the relationships between these three phenomena, asking when, how, why, and to what extent they reproduce one another. In the post-Civil Rights era, with (overt) racism now widely condemned, one challenge for social scientists is to conceptualize and measure its more subtle and diffuse manifestations and lasting effects.

Definitions

Racism cannot be defined without first defining race. Among social scientists, 'race' is generally understood as a social construct. Although biologically meaningless when applied to humans – physical differences such as skin color have no natural association with group differences in ability or behavior – race nevertheless has tremendous significance in structuring social reality. Indeed, historical variation in the definition and use of the term provides a case in point.

The term race was first used to describe peoples and societies in the way we now understand ethnicity or national identity. Later, in the seventeenth and eighteenth centuries, as Europeans encountered non-European civilizations, Enlightenment scientists and philosophers gave race a biological meaning. They applied the term to plants, animals, and humans as a taxonomic subclassification within a species. As such, race became understood as a biological, or natural, categorization system of the human species. As Western colonialism and slavery expanded, the concept was used to justify and prescribe exploitation, domination, and violence against peoples racialized as nonwhite. Today, race often maintains its 'natural' connotation in folk understandings; yet, the scientific consensus is that race does not exist as a biological category among humans – genetic variation is far greater within than between 'racial' groups, common phenotypic markers exist on a continuum, not as discrete categories, and the use and significance of these markers varies across time, place, and even within the same individual (Fiske, 2010).

For most social scientists, 'race' is distinct from 'ethnicity'. A major distinction is the assumption of a biological basis in the case of race. Races are distinguished by perceived common physical characteristics, which are thought to be fixed, whereas ethnicities are defined by perceived common ancestry, history, and cultural practices, which are seen as more fluid and self-asserted rather than assigned by others (Cornell and Hartmann, 2006). Thus, Asian is usually considered a 'race', whereas Tibetans and Bengalis are considered ethnicities. Although ethnicity and nationality often overlap, a nationality, such as American, can contain many ethnic groups (e.g., Italian-Americans, Arab-Americans). Yet, all three categories – race, ethnicity, and nationality – are socially constructed, and, as such, groups once considered ethnicities have come to be seen as races and vice versa. Moreover, some groups who are now taken for granted as 'white', such as the Irish, Italians, and Jews, were once excluded from this racial category. The definitional boundaries of race and ethnicity are shaped by the tug and pull of state power, group interests, and other social forces.

From a sociological perspective, it is this social construction of race – not its 'natural' existence – that is the primary object of inquiry in the study of racism. Bundled up with eighteenth century classifications of various racial groups were assertions of moral, intellectual, spiritual, and other forms of superiority, which were used to justify the domination of Europeans over racialized others. In the North American context, racist ideology served as justification for land appropriation and colonial violence toward indigenous peoples as well as the enslavement

of Africans starting in the sixteenth century. It was later used to justify the state-sanctioned social, economic, and symbolic violence directed at blacks and other minorities under Jim Crow laws. In the mid-twentieth century, the American Civil Rights Movement, global anticolonial movements, and increasing waves of non-European immigration to the West changed how individuals, groups, and nation-states talked about, viewed, understood, and categorized race. A major task for sociologists has been to assess these changes and their implications for racial discrimination and inequality.

Intellectual History

There are at least two distinct phases in the sociology of racism, demarcated by the changing nature of race and racism as constructed by social actors and social forces after World War II. The first phase – from the late nineteenth to the mid-twentieth century – typically considered racism as a set of overt individual-level attitudes; the second phase – from the mid-twentieth century to the present – considers racism as not simply explicit attitudes but also implicit biases and processes that are constructed, sustained, and enacted at both micro- and macro-levels. While the first phase focused on the direct relationship between racism and racial inequality, the second phase considers diffuse relationships between these concepts and the ways in which historical, unconscious, institutional, and systemic forms of racism interact with other social forces to perpetuate racial inequality.

In the late nineteenth century, as sociology emerged as a social scientific discipline, few scholars studied racism. (One notable exception was W.E.B. Du Bois, who analyzed the political economic roots of racism and its perverse impacts on Western institutions and psyches.) Instead of studying racism as a social problem, many social scientists – truly products of their time – maintained racist attitudes and incorporated racist assumptions into their explanations of racial group differences in social outcomes. Racism pervaded society, including sociology, and was legitimated by dominant scientific discourses such as Social Darwinism, which misapplied the concept of natural selection to the social world to account for why some (racial, class, etc.) groups excel more than others.

Beginning in the 1920s, when the scientific validity of 'race' came under closer scrutiny, some sociologists – primarily associated with the Chicago School – began to view racism as a distinct social problem worthy of study. The issue took on greater urgency during and after World War II when the devastating consequences of racism reached their ugly peak. This period can be characterized as the first phase in the sociological study of racism, in which dominant theories, drawing on psychology's emphasis on individual prejudice, conceived racism as a set of explicit individual-level beliefs and attitudes that were a historical relic (as opposed to a systemic social process) that would inevitably fade with time. This assumption of inevitable attenuation was most evident in theories of immigrant assimilation, which proposed an inexorable straight-line process, whereby 'ethnic' European immigrants originally racialized as 'other' would gradually assimilate into the American mainstream as full-fledged 'white' citizens.

In this first phase, defining racism as prejudicial beliefs and attitudes provided little difficulty for the social scientist, as individuals, organizations, and the state were explicit about how race mattered for the distribution of material and symbolic resources. For example, income inequality between whites and blacks could be readily explained by workplace discrimination and policies excluding blacks from well-paid jobs; differences in educational attainment could be explained by legally segregated schools; etc. The 1950s and 1960s, however, witnessed a shift in how individuals, groups, and nation-states used race in everyday life and social systems. In the West, the confluence of the Civil Rights Movement, increasing immigration, the fall of colonialism abroad, and the economic rise of developing nations coincided with the precipitous decline in overtly racist attitudes, as measured by representative opinion surveys. As racial prejudice declined (unevenly) in the United States and the world (Bobo et al., 1997), theories arose to explain why racism, racial discrimination, and racial inequality persisted, emerged, or changed form in some places more than others.

This moment may be characterized as the start of the second (and contemporary) phase in the sociological study of racism. It has witnessed the (re)emergence of once-ignored critical and structural analyses of racism (à la DuBois) as well as manifold new theories to account for the subtlety of present-day racism. These theories often focus on group-level processes and social structures as opposed to, or in interaction with, the individual. For example, whereas earlier scholars defined racism as primarily an individual problem of overt hostility that could be diminished through interracial interaction (e.g., Allport, 1954), later sociologists viewed racism as fundamentally rooted in political, economic, and/or status resource competition (e.g., Blalock, 1967; Blumer, 1958); under these conditions, intergroup contact could exacerbate the perceived group threat that, in this view, drives racial prejudice and discrimination (cf Nagel, 1995). Building on this latter perspective, other scholars have examined the intersections of racism with colonialism (e.g., Blauner, 1969), class conflict (e.g., Bonacich, 1972), and gender (e.g., Collins, 1990). In the 1980s and 1990s, various theories of 'new racisms' (see Section New Racisms) and implicit biases (see Section Implicit Bias) emerged, suggesting that racism itself has transformed into more covert forms. Sociologists have also elaborated theories of institutional racism (see Section Institutional Racism), exploring how racist ideologies and discriminatory practices have become embedded in taken-for-granted laws, policies, and norms that systematically (dis)advantage certain groups. And since the turn of the century, social scientists have turned attention to the social processes whereby race, racism, and racial inequalities are constructed and challenged at micro-, meso-, and macro-levels (see Sections Racism as a Social Process and Responses to Racism).

Contemporary Definitions of and Approaches to Racism

Contemporary approaches to racism center on explaining the well-documented persistence of racial inequality and racial discrimination in an era of declining overtly racist attitudes.

Without explicit ideologies of racial domination as a direct cause, how can we explain persistent racial inequalities in criminal sentencing, health, and wealth; persistent rejection of policies meant to alleviate racial inequalities; and persistent racial discrimination in hiring, credit markets, and housing (Bobo et al., 1997; Fiske, 2010; Massey and Denton, 1993; Pager and Shepherd, 2008)?

Various theories have arisen to account for this paradox. Some scholars point to the (alleged) cultural deficiencies of people of color – in particular, inner city blacks. These theories often acknowledge the history of racism in shaping contemporary inner city black culture but argue that subordinates' cultural behaviors are at least one immediate cause of continuing racial inequality (e.g., Moynihan et al., 1967; Patterson, 1998). Instead of focusing on the cultural problems of historically oppressed groups, other scholars have attempted to explain persistent inequality by showing how racism endures today – if not so much within individuals, then at least within institutions and organizations, and if not so much as explicit attitudes, then at least as implicit or covert biases. While some social scientists claim this 'broadening' of the concept of racism serves a 'political agenda' (van den Berghe, 2001: p. 12721), most consider it a necessity – offering an empirically and socially useful toolkit of approaches for understanding the durability of racial inequality in the twenty-first century. We now turn to these approaches.

New Racisms

One major line of work in the contemporary sociology of racism examines whether the observed decline in racist attitudes on opinion surveys represents an actual decline in racism or merely a decline in the social acceptability of expressing such attitudes; perhaps some individuals consciously hold racist attitudes but withhold them when surveyed. Since the 1970s, social scientists have developed various techniques – from more subtle questions to new forms of discourse analysis – to alleviate respondents' hesitancy to report socially undesirable attitudes and to draw out the deeper meanings behind ambiguous or contradictory responses.

Using these techniques, sociologists have uncovered new forms of racism that are expressed not in avowed racist attitudes but rather in contextually specific moral and symbolic principles that stereotype subordinated racial groups as undeserving and thereby justify existing racial inequalities. For example, surveys repeatedly show that many whites support racial equality in principle but resist policies to implement it (e.g., affirmative action and reparations). Kinder and Sears (1981) attribute this principle–implementation gap to 'symbolic racism', which merges a genuine belief in the universalistic principles of Western liberal democracy with stereotypes and moral resentments (rooted in childhood socialization) toward 'irresponsible' blacks. Bobo et al.'s (1997) concept of 'laissez-faire racism' also highlights persistent antiblack (and antinative) stereotyping and a tendency to blame blacks (and other minorities) for their social problems despite increased support for racial equality in principle. Unlike symbolic racism, however, they argue that (white) opposition to racial equality policies is rooted in perceived racial group threat (Blumer, 1958), which is "triggered when the dominant group's sense of entitlement to resources and privileges appears threatened by subordinate group gains or aspirations" (Denis, 2012: p. 456). Similarly, 'colorblind racism' refers to a set of frames, styles, and scripts that are used to explain and justify the racial status quo without sounding racist (Bonilla-Silva, 2010). (For additional variations on the new racism theme, see Quillian, 2006.)

Despite this outpouring of research and theorizing, some critics (e.g., Sniderman and Carmines, 1997) argue that the problem is not 'hidden' racist sentiments or cultural stereotypes; rather, many whites reject policies such as affirmative action because of principled opposition to government intervention. Yet, regardless of whether racism or 'political principle' directly motivates opposition to policies intended to advance racial equality, such opposition effectively replicates racial inequality (see Section Institutional Racism). In short, although the observed decline in overt racist attitudes shows that racism is socially unacceptable in much of contemporary society, the extent to which individuals still hold racial stereotypes, prejudices, or ideologies – and the precise form(s) these take – remains contested.

Implicit Bias

Another explanation for persistent racial discrimination and inequality despite the decline in overt racist attitudes can be found in the growing literature on implicit bias. An implicit bias is an unconsciously triggered belief in the inferiority of, or negative attitude toward, a group(s). The assumption, drawing from recent findings in cognitive psychology and its nascent interaction with cultural sociology, is that implicit biases can impact expectations and actions. As such, unconscious negative beliefs and feelings about racial groups may not appear on a survey but may be revealed in everyday interpersonal interactions at work, at school, or on the street.

Relying on psychological experiments, and an Implicit Association Test (IAT), scores of studies have considered the association between race and various attributes and judgments, revealing that, on average, individuals more readily associate positive attributes and stereotypes with whites than with other races, particularly blacks (Banaji and Greenwald, 2013). Furthermore, these biases predict distinct (especially spontaneous, nonverbal) behaviors and emotions that could affect interpersonal interaction (Lane et al., 2007). More recent work has shown that minorities (not just whites) sometimes hold implicit biases against their own group despite articulating explicit beliefs in racial equality (Livingston, 2002). The implicit antiblack biases of many blacks, for example, may be interpreted as a form of internalized racism, in which members of a subordinated racial group accept the negative stereotypes and attitudes toward their group. While inquiry into internalized racism has been criticized as victim blaming and racially essentialist, Pyke (2010) argues that this work is critical to understanding the mechanisms whereby racial inequality is reproduced and can even be empowering, as it demystifies an insidious element of white privilege and systems of power.

Research on implicit biases has its limitations. Some scholars have questioned the reliability and validity of the IAT. Others suggest that laboratory experiments on nonrepresentative participants may not generalize to real-world contexts

where behavioral and attitudinal dynamics may differ. Moreover, studies of implicit biases would benefit from deeper engagement with macrosociological research on the media and other institutions that could shape implicit attitudes, and new institutional theories that view contemporary workplaces as contexts in which ostensibly neutral scripts and procedures could moderate autocognitive processes.

Racism as a Social Process

The upheavals of the post–World War II period made plain the mutability of racial classifications and racism. While research on new racisms and implicit biases documents the changing content, character, and implications of new forms of racism, another line of scholarship seeks to identify and explain the social processes and actors that account for change (and persistence) in racism. Within this broad, process-based approach there are two major lines of research – one that considers racism in historical context, focusing on general mechanisms that account for macrolevel changes over time, and another that considers microsocial processes that operate in interpersonal interaction.

The term 'racialization' tends to designate theories of racism as a macrolevel historical process. Racialization is the process of constructing racial meaning, including the creation of racial categories and the signification of these categories in relation to people, objects, and ideas (Murji and Solomos, 2005; Satzewich, 2011). Racialization's focus on the constructedness of racial meaning shifts analytic attention away from the content of racism and toward the individuals, groups, and social forces constructing and signifying race. The increasing focus on racialization, as a process, is part of the growing sociological focus on uncovering general social processes and mechanisms (Lamont et al., 2014). Indeed, research on racialization has revealed fundamental processes and mechanisms that contribute to the persistence of system-wide racial inequalities – from cognitive classification processes that allow humans to identify and categorize others (Massey, 2007) to nation-state bureaucracies and methods (such as the census or standardized education) that categorize, define, and distribute resources to groups at the macrolevel (Omi and Winant, 1994; Wimmer, 2013). One benefit to the study of racism as a social process is attention to the fluidity of racial categorizations and their embeddedness in power relations (e.g., Saperstein and Penner, 2012). One difficulty of macrolevel approaches is their tendency to present 'grand' narratives that abstract or totalize the way race operates. We may lose explanatory precision on the nuanced operation of race in particular contexts, institutions, and organizations at particular times and places (see Hall, 1980 on 'historically specific racisms').

Another process-oriented approach considers how microlevel social processes maintain and change racial categories, stereotypes, attitudes, and beliefs. Drawing on Goffman and the symbolic interactionist tradition, some scholars explore how racial identities and statuses are embodied and enacted in interpersonal interaction through distinctive habits, styles, scripts, and modes of self-presentation that inadvertently reproduce racial inequalities (e.g., Anderson, 2000). More broadly, Schwalbe et al. (2000) have identified generic processes in face-to-face interaction and meaning-making pursuits – othering, subordinate adaptation, boundary maintenance, and emotion management – that create and reproduce inequalities, including racial inequalities. Similarly, cultural sociologists examine how symbolic boundaries are constructed against racialized others, often translating into social, spatial, and temporal boundaries at the mesolevel (e.g., neighborhood) that perpetuate racial segregation (e.g., Small, 2004). In a small-town ethnography, Denis (2015) illustrates how the mutually reinforcing processes of subtyping, ideology-based homophily, and political avoidance norms enable many white Canadians to maintain laissez-faire racist attitudes, despite frequent positive contact with indigenous peoples. In social psychology, status characteristics theory considers how status characteristics (e.g., race, gender, and age) shape the influence and prestige of individuals in small group settings; it highlights the role of self-fulfilling prophecies, as lower status members are viewed and treated in terms of, and may even conform to, the stereotypical low expectations of their group (Fiske, 2010). While setting aside the question of why 'race' initially became a salient marker, all of these microlevel studies offer insights into how racial inequalities and stereotypes are reproduced in concrete settings. Much of this work also considers the everyday responses of historically marginalized groups to racism, and how these responses perpetuate or challenge the racial status quo (see Section Responses to Racism).

Institutional Racism

One major departure from past scholarship is contemporary sociology's shift from locating racism in individual beliefs and attitudes to considering it as primarily a phenomenon of higher-level entities, such as social processes, social forces, and institutions. Rather than explaining racial inequality via individual-level racism (conscious or otherwise), theories of institutional racism give analytic primacy to the taken-for-granted policies, practices, and norms of organizations, systems, and structures.

First defined by Stokely and Hamilton (1967), institutional racism refers to particular and general instances of racial discrimination, inequality, exploitation, and domination in organizational or institutional contexts, such as the labor market or the nation-state. While institutional racism can be overt (e.g., a firm with a formal policy of excluding applicants of a particular race), it is more often used to explain cases of disparate impact, where organizations or societies distribute more resources to one group than another without overtly racist intent (e.g., a firm with an informal policy of excluding applicants from a low income, minority neighborhood due to its reputation for gangs). The rules, processes, and opportunity structures that enable such disparate impacts are what constitute institutional racism (and variants such as 'structural racism', 'systemic racism', etc.).

The literature on institutional racism is diffuse but coheres on the point that macrostructural processes, as opposed to individual acts, provide more meaningful explanations of contemporary racial inequality. Bonilla-Silva's (1997) structural conception of racialized social systems' emphasizes how political, economic, and social arrangements are structured by racial hierarchy and supported by colorblind ideology.

Similarly, Feagin (2010) analyzes the institutional spaces, societal norms, and 'white racial frames' that can be traced back to sixteenth century slavery and imperialism, concluding that American society is fundamentally racist. Another variant is the (internal) colonialism model, in which one racialized group imposes its ideas, systems, and lifestyles on another via policies (such as Canada's Indian Act) and practices (such as the Indian residential school system) that are justified by the former group's presumed superiority (Frideres and Gadacz, 2008). These conceptions of institutional racism and systemic racial/colonial oppression are similar to macrohistorical process-centered conceptions in their totalizing nature (see Section Racism as a Social Process); they suggest that race and racism operate on various levels and in various corners of the social system, which is 'racialized' as such. They have been criticized for downplaying diversity within both dominant and subordinate groups, whose life chances vary considerably by class, gender, and other crosscutting categories (Satzewich, 2011).

Alternative approaches to institutional racism are less totalizing. Audit studies, for example, seek to measure racial discrimination at the firm or organization level by sending equally qualified resumes or research participants to employers, creditors, landlords, and the like. These studies have found that racial discrimination still exists in hiring, credit, and housing markets (Quillian, 2006; Pager and Shepherd, 2008). While audit studies suffer from uncertain generalizability (case studies do not tell us about all firms) and cannot specify the mechanisms that account for racial discrimination (e.g., is it due to employers' covert or implicit biases or uncontrolled differences between research participants?), they do enable us to identify the precise levels of discrimination in specific firm contexts. Moreover, when coupled with complementary evidence about labor market processes, such as Kirshenman and Neckerman's (1991) analysis of employers' statistical discrimination, we gain insight on important avenues through which racial discrimination and inequality persist.

Still other approaches focus on state and nonstate institutions – such as the criminal justice and education systems and the media – assessing the rules, regulations, norms, laws, discourses, and procedures that account for pernicious and racialized differential treatment and outcomes. While an institutional racism perspective highlights the general systems and processes that maintain racial inequality, one criticism is that it dilutes the meaning of racism (Miles, 1989) and attaches moral condemnation where it is undue (van den Berghe, 2001). Is it fair, or even accurate, to label an institution, organization, or society 'racist' if such intent is lacking? On the other hand, Allport (1954: p. 12) reminds us, "The unpleasant flavor of a word should not mislead us into believing that it stands only for a value-judgment"; the point of these theories is not to blame the innocent but to improve understanding so that the policies, practices, and ideas that perpetuate racial inequality can be identified and dismantled. Conversely, institutional racism's focus on the extraindividual might obscure and absolve the role of individual actors in maintaining racism.

Responses to Racism

While the contemporary sociology of racism focuses mostly on the processes, people, and organizations that perpetuate racism, increasing attention is being paid to those who experience racism. The literature on internalized racism (see Section Implicit Bias) illuminates how the targets of racism may accept dominant racist ideologies and engage in habitual interactions that perpetuate their own subordination. Yet, a growing literature also interrogates the multiple experiences, knowledges, and practices of subordinated racial groups. Increasingly, studies of 'everyday racism' (Essed, 1991) and responses to stigmatization (Lamont and Mizrachi, 2012) are providing insights into the effects of, responses to, and strategies for combating various forms of racism.

In one groundbreaking study, Essed (1991) examined how black women in the Netherlands and California navigate everyday racism, showing how it covertly shapes their daily life routines but also illuminating their diverse and often subtle forms of resistance. She argues that these women's narratives are important knowledge *ipso facto* because their unique social positions and experiences (raced, classed, gendered, etc.) offer unique perspectives on the inner workings of oppression and resistance (cf Collins, 1990); from a sociology of knowledge standpoint, subordinated groups' knowledge serves as a corrective to the elite, Western knowledge systems of dominant social scientists (Feagin, 2010). Building on this work, Lamont and Mizrachi (2012) systematically compare the responses of stigmatized groups in Brazil, Israel, and the United States, arguing that the comparative study of responses illuminates how institutions, ideologies, and varying national contexts constrain and enable individual opportunities. Other scholars have assessed antiracist and multicultural policies and affirmative action and diversity programs at the state and organizational levels (e.g., Henry and Tator, 2010). Still others have examined the conditions under which racial minority groups and their allies mobilize in social movements for racial justice (e.g., McAdam, 1982).

This (increasingly comparative and cross-national) work on responses to racism has blossomed alongside a robust sociology of immigration literature, which highlights the agency of immigrants in shaping their incorporation into host societies (Alba and Nee, 2003). Different immigrant groups employ varying strategies, seize unique opportunities in the form of ethnic niches, and encounter different obstacles. Contemporary assimilation is variegated and the incorporation of new, often racialized, groups has proven anything but straightforward. Moreover, competition and tension between native-born minority groups and recent immigrants has highlighted racial discrimination between subordinate groups (Bobo and Hutchings, 1996; Waters et al., 2014). Indeed, the relative ease with which some immigrants (despite being racialized) have integrated into the mainstream economically and socially only underscores the uniquely pernicious nature of antiblack and anti-indigenous racism in North America (Dixon, 2006). Numerous studies, for instance, have documented the stigmatization and racism faced by upwardly mobile middle-class blacks (e.g., Feagin and Sikes, 1995) and indigenous peoples (e.g., Denis, 2012), as well as the creative strategies they use to cope with and respond to racism.

One criticism of these studies is that they appear to place the burden of overcoming racism on the shoulders of the targets of racism rather than on the actors and institutions that perpetuate it. Yet, until racism is eliminated, it is important to

investigate how the targets interpret and respond to it in order to understand how racism affects them, ensure their voices are heard, and develop more effective strategies to combat racism itself.

Challenges and Future Directions

'Racism' today is a dirty word; yet, significant racial inequalities in socioeconomic, health, and other outcomes persist; racial minorities around the world continue to report frequent experiences with racial discrimination; and racial flashpoints – from the recent backlash to First Nations protests in Canada, to the Trayvon Martin shooting and trial in the US, to ongoing European debates over immigration reform – abound. Our contemporary moment presents theoretical and methodological challenges. What is the most productive way to study race and racism in an era when openly espousing racist views is anathema?

Rather than simply studying overt categorical hostility or explicitly racist laws and their effects, some sociologists have developed more nuanced understandings of what racism means, how it operates, and how it relates to racial inequality. These concepts include the multidimensional 'new racisms' (laissez-faire, colorblind, etc.), systemic and institutional racism, and even unconscious or implicit racism, which are often studied through experiments, audit studies, critical discourse analysis, and other innovative techniques. Other scholars eschew consideration of the proper definition of racism and instead examine the processes that construct racial categories, responses to racism by historically marginalized groups, and the (deliberate) strategies and (taken-for-granted) routines that reproduce (or challenge) racial inequalities.

From a pluralistic and pragmatic standpoint, we urge continued attention on all fronts. Greater interchange between these literatures should also lead to creativity and innovation as scholars seek to bridge levels of analysis and make sense of seemingly contradictory themes and trends. Although some scholars decry the conceptual broadening of 'racism', the sociology of racism is best served by this pluralism. As Western countries incorporate more 'nonwhite' immigrants and racial boundaries collapse, transform, and (re)emerge, scholars must use multivalent approaches to gain a comprehensive understanding of the nature, causes, and consequences of contemporary racism, racial discrimination, and racial inequality.

Racism: Social Psychological Perspectives

Martha Augoustinos, School of Psychology, University of Adelaide, Adelaide, SA, Australia

Abstract

Racism has been a core topic in social psychology since the 1930s. Central to most definitions of racism is the belief in a biological hierarchy between different social groups based on perceived racial differences. As a complex social issue multiple social psychological perspectives have been advanced to understand and theorize beliefs, behavior, and social practices that sustain racial inequality ranging from the individual to the social level of explanation. These include personality theories; social cognition models; realistic group conflict; social identity theory; critical discursive approaches, studies of White privilege; and embodied racism. Although these perspectives are frequently argued to be inconsistent with each other, recent attempts at integration are providing richer accounts of this phenomenon.

Defining Racism

Although many definitions of racism have been proposed, an all-inclusive definition has yet to be agreed upon, particularly as researchers have identified a variety of 'racisms' (Miles and Brown, 2003; Richards, 1997). Central to most definitions of racism is the belief in a biological hierarchy between different social groups based on race, and the associated practices that maintain and reproduce social inequalities between groups based on such beliefs. The belief that different racial groups reflect a natural evolutionary hierarchy, at the top of which are European (White) people was central to scientific racism which was widely promoted as an ideology between 1850 and 1910. During this period, European imperialist expansion and colonial rule over Indigenous peoples created the ideal conditions for the proliferation of such Social Darwinist beliefs (Richards, 1997).

The concept of race is entrenched in both popular usage and scientific discourse as a taken-for-granted, essentialist category that categorizes people into groups based on assumptions that surface phenotypic characteristics such as skin color reflect deeper genotypic features. Despite its ubiquitous taken-for-granted usage, geneticists and biologists discredited the validity of race as a scientific category as long ago as the 1930s (Richards, 1997), and more recently via the mapping of the human genome (McCann-Mortimer et al., 2004). Nonetheless the concept of race continues to be used uncritically both in the scientific community and in everyday discourse as a 'natural' kind variable in ways that reinforce the commonplace view that it is a biological and genetic reality that reflects real differences between groups.

Although the notion of a biological hierarchy between groups is generally eschewed today and indeed is associated with blatant forms of racism, it has been replaced with beliefs in a cultural hierarchy between groups where the dominant group's social values, norms, and practices are represented as superior to those of less dominant groups. As we will discuss further below, this has come to be known as the 'new racism.' Group differences therefore, whether biological or cultural, continue to operate as socially meaningful cues by which to categorize and differentiate people. That is, 'race' has become a reified and objectified social representation through which group differences come to be understood and explained (Moscovici, 1988).

Prejudice versus Racism

There has been a tendency within psychology to use the terms prejudice and racism interchangeably. Jones (1997), among others, argues that racism is distinct from prejudice. Prejudice has commonly been defined as negative attitudes and behavior toward a social group and its members. Prejudice is typically regarded as an individual phenomenon, whereas racism is a broader construct that links such individual beliefs and behavior to broader social and institutional norms and practices that systematically disadvantage particular groups. The second important difference between prejudice and racism relates to the role of power. At an individual level, a person can display prejudice, but this in itself does not necessarily constitute racism. Central to racism is the ability of dominant groups to systematically exercise *power* over outgroups. If we define racism without reference to power differentials between groups, it is clear that anyone can engage in ingroup preference and outgroup bias. 'Everybody is racist' is a claim that is often used to counter accusations of racism (Hage, 1998). Importantly, the power one group has over another transforms prejudice into racism and links individual prejudice with broader social practices (Jones, 1997).

Racism, practiced at a structural and cultural level, maintains and reproduces the power differentials between groups in the social system. Racism practiced at this broad societal level has been referred to as institutional and cultural racism (Jones, 1997). Institutional racism refers to the institutional policies and practices that are put in place to protect and legitimate the advantages and power one group has over another. Institutional racism can be overt or covert, intentional or unintentional, but the consequences are that racist outcomes are achieved and reproduced. Cultural racism occurs when the dominant group defines the norms, values, and standards in a particular culture. These mainstream ideals permeate all aspects of the social system and are often fundamentally antagonistic with those embraced by particular minority

groups. To participate in society, minority groups often have to surrender their own cultural heritage and adopt those of the dominant group (e.g., the White majority).

Although prejudice has been condemned within psychology as negative and pernicious, it has also been criticized for depoliticizing the issue of racial inequality. Because the concept of prejudice is primarily seen as located within the psychology of the individual, it fails to recognize the wider historical, social, and institutional structures that support racial inequality. Because of this narrowness, the concept of prejudice is often challenged as actually part of the problem of racial inequality – by making it an individual pathology rather than a political and social reality. As many social theorists have argued, this has had the net effect of obscuring the political and ideological dimensions of prejudice. Racism can persist in institutional structures and policies in the absence of prejudice at the individual level (Henriques, 1984).

New Racism

Over the past 50 years, social psychologists and social scientists more broadly have argued that contemporary racism has become less about beliefs in a biological hierarchy between groups, and increasingly about beliefs in the cultural superiority of a dominant group's values, norms, and practices (Barker, 1981). Survey studies consistently demonstrate that blunt, hostile, segregationist, and White supremacist beliefs are less openly acceptable to White majority group members in Western liberal democracies. However, racial inequality continues to exist. To explain this, a distinction is therefore commonly made between 'old-fashioned racism' and 'modern' (McConahay, 1986) or 'symbolic racism' (Kinder and Sears, 1981), which in contrast, is subtle, covert, and paradoxically, endorses egalitarianism. Modern racism rejects racial segregation and notions of biological supremacy, and is instead, based on feelings that certain social groups transgress important social values such as the work ethic, individualism, self-reliance, and self-discipline: values that are embodied in the Protestant ethic. Symbolic or modern racism justifies and legitimates social inequities based on moral feelings that certain groups violate such traditional values.

Gaertner and Dovidio (1986) have also proposed models of racism that address the changing and complex nature of contemporary beliefs about race. Their 'ambivalent racism' and 'aversive racism' models both posit that contemporary racial attitudes have become complex, contradictory, and multidimensional. In the ambivalent racism model, pro-Black and anti-Black sentiments are seen to coexist within the person and to reflect different value structures held by the individual. Pro-Black attitudes reflect humanitarian and egalitarian values that emphasize equality and social justice, whereas anti-Black attitudes reflect individualism, the Protestant ethic, hard work, individual achievement, and self-reliance. Similarly, the aversive racism model emphasizes the coexistence of a contradictory complex of attitudes: on the one hand, liberal egalitarian principles of justice and equality; and on the other, a residue set of negative feelings and beliefs about particular groups that are learned early in life, and which are difficult to completely eradicate. Gaertner and Dovidio (1986: p. 63) describe these negative feelings as "discomfort, uneasiness, disgust, and sometimes fear, which tend to motivate avoidance rather than intentionally destructive behaviors." In both of these accounts, individuals strive to maintain a nonprejudiced image, both to themselves and to others, and struggle unconsciously to resolve the internal psychological ambivalence that is produced by maintaining a contradictory set of attitudes and beliefs. By justifying and legitimating social inequalities between groups on the basis of factors other than race, members of dominant groups can avoid attributions of racism and thus maintain and protect a nonprejudiced self-image. Indeed the psychological and social motivation to dodge a prejudiced identity is a common thread in contemporary theorizing on racism.

Contemporary racism, therefore, is seen as more insidious and difficult to identify because of its subtle and covert nature. This has led to the proliferation of implicit measures to identify and measure this more subtle racial bias (Greenwald et al., 2003). For example, the Implicit Association Test is a response latency measure using subliminal primes to test the strength of association between social categories (e.g., 'Black' or 'White') and positive and negative trait characteristics. Slower responses to stereotype inconsistent associations (Black + positive traits and White + negative traits) than to stereotype consistent associations (Black + negative traits and White + positive traits) is treated as evidence for an implicit bias or prejudice toward Blacks. Indeed the distinction between implicit and explicit racial bias is now so ubiquitous in social psychology that it is sometimes (erroneously) assumed that implicit measures reflect people's true or real attitudes whereas explicit measures merely reflect social desirability norms. It has been argued, however, that implicit measures do not tap racial attitudes or beliefs per se but deeply ingrained stereotypes strongly associated with particular groups. Devine's (1989) dissociation model of prejudice is consistent with this view and posits that stereotypes are more primitive cognitive structures learned early in life that can be automatically activated, whereas racial attitudes (prejudice) are learned later in life and can be either inconsistent or consistent with these stereotypes. The fact that negative stereotypes can be unconsciously activated even among people with low levels of explicit prejudice should not be taken as evidence that prejudice is an inevitable and natural cognitive tendency in everyone. As we will discuss below, the inevitability of prejudice perspective is associated with cognitive models of prejudice.

Theories of Racism

A variety of explanations for prejudice and racism have been advanced by social psychologists throughout the twentieth century. The prevalence of particular kinds of explanations has shifted during this time depending on wider historical and social factors and the dominance of specific paradigmatic frameworks within social psychology itself. Here we provide an overview of six current approaches to racism ranging from the individual to the social level of explanation: personality theories; social cognition models; realistic group conflict and social identity theory; critical discursive approaches, studies of White privilege; and embodied racism.

Personality Theories

Freudian psychodynamic accounts of prejudice were prevalent between 1930 and 1960. Prejudice was largely understood as a product of intrapsychic unconscious impulses primarily related to sexual and aggressive desires within the person. To reduce tension, negative emotions such as fear, anger, and disgust generated by these internal psychological conflicts are projected outward onto outgroups.

The most well known of these psychodynamic approaches is *The Authoritarian Personality* by Adorno et al. (1950). Published soon after the end of the Second World War, Adorno et al. were interested in explicating a theory that accounted for the widespread support for fascism as was seen in Nazi Germany. Adorno et al. (1950) argued that parent–child relationships with severe and punitive parental discipline produce children with an authoritarian personality characterized by a rigid adherence to conventional social values and mores, an unquestioning subservience to one's moral and social superiors, and a vigilance for, and hostile rejection of, those who violate conventional social values and mores. The F Scale was developed to measure levels of authoritarianism and was widely used as a personality measure. High levels of authoritarianism were found to be associated with all types of prejudice (racism, sexism, homophobia). Despite the widespread use of the F Scale, by the 1960s, the theory of the authoritarian personality was strongly criticized for its emphasis on internal psychological predispositions at the expense of social and cultural norms that tolerated prejudice and sanctioned institutionalized racism, for example, racial segregation in the United States and apartheid in South Africa (Pettigrew, 1958).

Interest in authoritarianism was revived in 1981 with Altemeyer's theory of right-wing authoritarianism (RWA). RWA is described as a rigid adherence to social conventions, submission to established authorities, and a strong rejection of outgroups who are perceived to be culturally and ethnically different. Unlike Adorno et al. whose work was heavily influenced by psychodynamic theory, Altemeyer theorized RWA as an individual personality characteristic that was predominantly shaped by social learning experiences. RWA has been found to be a good predictor of racial and ethnic prejudice in a variety of different settings, more so than the early authoritarianism scales.

The most recent personality approach to prejudice is that of 'social dominance orientation' or SDO (Sidanius and Pratto, 2001). SDO is purported to be a stable individual difference that refers to a person's level of support for group-based hierarchies in society such as racial/ethnic, gender, and socioeconomic hierarchies. Like RWA, SDO is strongly correlated with prejudice. SDO scores vary with gender (males score higher), personality and temperament, education, religion, and whether one is a member of a dominant or subordinate group. Although the concept of SDO is embedded within a wider social theory, it too has been criticized for reducing prejudice to a psychological trait rather than a social phenomenon that requires a social/structural explanation. Perhaps the most controversial aspect of SDO is the claim that group-based hierarchies and the legitimating beliefs that support them have an evolutionary basis.

Significant limitations have been identified with personality accounts of prejudice. Most notably is the issue of why certain groups rather than others become the targets for prejudice by authoritarians, those high on RWA and/or SDO. In addition, although such theories recognize that economic, historical, and social factors contribute to these predispositions, the potential interplay between individual psychology and social structural factors is rarely dealt with explicitly or integrated thoroughly into these models.

Social Cognitive Theories

Gordon Allport's seminal work, *The Nature of Prejudice* (1954), provides the foundational basis for social cognitive models of prejudice which have become dominant and influential in social psychology since the 1980s. Allport's definition of prejudice as "an antipathy based upon a faulty and inflexible generalization" (1954: p. 9), about a social group and its members emphasizes the prominent role that social categorization and stereotyping as perceptual–cognitive processes are given in social cognition models. According to these models, categorizing people into their respective group memberships (such as race, gender, age) is driven by our cognitive need to simplify the overwhelming amount of stimulus information we receive from our environment. This group-based or category-based perception is seen as distorting reality because people are not viewed as individuals in their own right but rather as prototypical group members. In turn, this leads to stereotyping, which recent social cognition research suggests can occur automatically and outside conscious awareness (Nosek et al., 2011). Stereotyping of course is just one step away from prejudice – literally prejudging someone based solely on their group membership. This inextricable relationship between categorization, stereotyping, and prejudice is central to social cognition models of prejudice and notwithstanding some of the qualifications that recent research has placed on this directional, and by implication, causative link between these three processes (e.g., Devine, 1989, see above), it is nonetheless the case that categorization in and of itself is seen as the cognitive basis for prejudice, driven primarily by our limited processing capacities.

Social cognition models have been criticized for normalizing prejudice and racism as inevitable products of our cognitive hard-wiring. Critics have also argued that by treating racial categories and racial categorization as natural rather than social and ideological constructs, social cognition models themselves reproduce racism in psychology (Hopkins et al., 1997).

Realistic Group Conflict and Social Identity Theory

Realistic group conflict theory and social identity theory are intergroup approaches to racism in social psychology that emphasize the role that relations of power and dominance between different social groups play in determining patterns of intergroup hostility. As the name suggests, realistic group conflict views intergroup hostility as arising from competition between social groups for economic, social, and cultural resources. Unlike personality theories that see racism and

prejudice as outcomes of internal psychological drives or differences in personality, in this approach conflict is viewed as emerging from 'real' group-based interests. The famous boys' camp field studies by Sherif et al. (1961) demonstrated how the creation of two competing groups was able to produce ingroup favoring and outgroup derogating attitudes and behavior between the two groups. When the social conditions were changed, however, and the two groups were required to cooperate to obtain resources or to complete valued tasks, intergroup hostility began to diminish.

Another series of famous studies, the minimal group experiments by Henri Tajfel and his colleagues formed the foundations upon which social Identity theory (SIT) was built (Tajfel and Turner, 1986). Many social psychologists have concluded erroneously from the minimal group experiments that the mere categorization of people into ingroups and outgroups is sufficient to trigger intergroup discrimination and prejudice. Although SIT stresses the psychological importance for groups to differentiate themselves positively from other groups this does not necessarily go hand-in-hand with ingroup enhancement and outgroup derogation though regrettably these are all too frequent occurrences. Groups can maintain a positive social identity without threatening the social identity of others. SIT posits that groups and their members strive to achieve some sort of differentiation from other groups, in ways that are shaped by the nature of the intergroup context and on dimensions of importance to them. Sometimes those dimensions of importance emphasize tolerance, generosity, and beneficence, but again all too often these dimensions emphasize superiority, dominance, and preserving ingroup privilege (Ellemers and Haslam, 2012).

Critical Discursive Research

Critical discursive research views racism as interactive and communicative and as located within the language practices and discourses of a society. This body of work emphasizes the ambivalent and contradictory nature of contemporary racism, but explicitly avoids making claims about the psychology of individual perceivers. Discursive studies analyze how people talk, discuss, and debate matters to do with 'race' and intergroup relations in both formal and informal settings (van den Berg et al., 2003).

It is through everyday language practices, both in formal and informal talk that relations of power, dominance, and exploitation become reproduced and legitimated. The analytic site for discursive research is how discursive resources and rhetorical arguments are put together to construct different social and 'racial' identities, and to provide accounts that legitimate these differences and identities as 'real' and 'natural.' Discursive studies locate these language practices or 'ways of talking' at a societal level, as products of a racist society rather than as individual psychological and/or cognitive products. The analytic site therefore is not the prejudiced or racist individual, but the discursive and linguistic resources that are available within an inequitable society (Wetherell and Potter, 1992). This approach has been able to identify how linguistic resources are combined in flexible and contradictory ways to reproduce and justify racist outcomes in modern liberal democracies. In some instances, existing relations of power, dominance, and privilege are maintained through overt racial ideology, but given the increasing opprobrium against the expression of such views, social inequalities are more commonly legitimated through the flexible and contradictory use of liberal egalitarian arguments that draw on principles such as freedom, individual rights, and equality. Discursive studies in several Western countries including Australia, Britain, Belgium, the Netherlands, New Zealand, and the United States have demonstrated how majority group members express negative and even hostile views of minorities by the use of self-sufficient rhetorical arguments premised on liberal and egalitarian values such as treating everybody equally.

Critical discursive research has demonstrated the varied ways the category of racism is itself highly contested in everyday life: that is, defining what is and what is not racist is far from being a value-free, neutral assessment. Rather, the category of racism itself is constructed flexibly and variably, and can be used to manage the moral accountability and identity of an individual or group. van Dijk (1992) documents the ubiquitous nature of denials of racism through the use of disclaimers such as "I'm not racist but … ." Contemporary race talk therefore, is strategically organized to deny prejudice and racism. By redrawing the boundaries of what may be legitimately defined as 'racist,' the category of racism may be used to position a person or group as 'not racist' by placing their own behavior and views outside of these boundaries.

These language practices are forms of power that are products of particular historical, hierarchical relationships between groups of people, in which some people have unjustly and unfoundedly claimed dominance over others. Understood as power relationships, racism shapes the lives of everyone within these hierarchies, both the oppressed and the oppressors. In this sense, 'race' is a form of categorization that reflects particular forms of power relations between groups of people, rather than reflecting the actual attributes (whether they be physical or behavioral) of any particular group of people.

Embodied Racism

While critical discursive research has been invaluable for elucidating the perpetuation and legitimation of racism, it has also been criticized for its privileging of discourse; for ignoring the materiality of oppression. Discursive work has tended to become heavily involved in identifying the rhetorical aspects of racism and oppression, but has been less concerned with the nexus between discourse, space, and place. Such a research focus has been taken up by Durrheim and Dixon (2005) in South Africa.

Durrheim and Dixon (2005) combine discourse analysis with ethnographic mapping to identify the ways in which discourses are embodied in people's use of public places such as beaches. They demonstrate that, even in post-Apartheid South Africa, there remains significant physical segregation on South Africa's beaches – Whites and Blacks use different areas of the beach, and use the beach at different times. These spatial practices are legitimated through discourses about 'appropriate beach behavior' with White beach-goers explaining that they leave the beach because Black beach-goers are too loud, create mess, and do not respect personal space. Their

research demonstrates the interdependence of discourse and embodied practices and how "'race relations' are constructed both in language and in located bodily practices, emphasising how people describe and account for the racialised features of social life that they participate in" (Durrheim and Dixon, 2005: p. 459). They argue that without such a combined approach, research on racism cannot capture the lived experience of racism, or of anti-racism. Their observations and interviews capture the ongoing nature of racism in everyday life, even where overt official structures maintaining inequality are dismantled.

Racism as White Privilege

While traditional research on racism focuses on attitudes and practices toward minorities, recent research on White privilege turns the gaze from minorities to the majority group. Thus there is a shift in focus – the gaze moves away from those who bear the brunt of racism, and toward the discourses and institutional practices of those who benefit from racism (Aveling, 2004). This body of work focuses on White identity construction (e.g., Carter, 1997). It also examines the ways in which whiteness is produced and reproduced in different social and cultural sites; and the implications of these constructions for intergroup relations and anti-racism (e.g., Hage, 1998). Whiteness studies is primarily concerned with how White people's identities are shaped by broader institutionalized forms of racism and brings to the fore both the benefits that White people accrue because of their privileged position in society and the responsibilities they have for addressing racism (Giroux, 1997).

Clearly the category 'White' or 'White people' is problematic as a way of referencing the dominant majority in Western liberal democracies as it fails to adequately reflect the ethnic and cultural heterogeneity of group members that may identify as 'White.' Nonetheless by marking 'whiteness' (not only as a category of skin color, but of cultural capital (Hage, 1998)), there is an attempt to make visible the unearned power and privilege that accrues to the dominant majority, especially those that have access to the highest cultural and social capital – in terms of appearance, ancestry, religion, socioeconomic status, education, and employment (Hage, 1998).

Broadly speaking, whiteness is "… the production and reproduction of dominance rather than subordination, normativity rather than marginality, and privilege rather than disadvantage." In this definition, whiteness is something that places White people in normative positions and grants White people unfair privileges. These positions and privileges are often invisible to White people, because of this normativity. Indeed, it is this normativity that gives whiteness its power (Frankenberg, 1993: p. 236).

Integrating Multiple Perspectives

This overview of social psychological approaches to racism always raises the difficult question of whether it is possible to integrate these different theories. This question has always been a bone of contention within psychology, as analytic frameworks differ significantly in their epistemological assumptions and orientations. It also raises the question of whether integration is desirable.

Duckitt (1992) argues that these multiple social psychological perspectives are not necessarily competing paradigms, but rather each is a valid response to different aspects of this social phenomenon: unconscious processes, personality, cognitions, social norms and linguistic practices, power, social structure, and intergroup relations.

Duckitt (1992) has proposed an integrative framework that identifies four primary causal processes of prejudice: internal psychological processes; social and intergroup dynamics; social transmission; and individual differences. He argues that each of these causal processes provides a partial but essential contribution to the explanation of prejudice: psychological processes build a human propensity for prejudice; social and intergroup dynamics elaborate this propensity into socially shared patterns of interaction; these patterns are socially transmitted throughout social groups; and individual differences in susceptibility to prejudice modify these social norms. Each theory is limited on its own as it focuses on and seeks to elaborate just one of these causal processes.

While Duckitt's integrative framework has considerable appeal more recent critical approaches that focus on racial discourse, power, whiteness, and embodiment are largely ignored in this model. Bringing all of these together we conclude that social psychology has conceptualized racism to be a normative, often invisible system of social practices, cognitions, emotions, and discourses that are perpetuated through all levels (individual, interpersonal, intergroup, institutional) that privilege one social group and disadvantage and marginalize other social groups. These practices can be overt assertions of biological difference, but in today's social and political climate, are more likely to be covert and implicit.

Radical Social Work

Abstract

Social work's legacy of 'progressive politics' or radical traditions shifts according to changes in political, economic, and social environments. Working on social justice becomes an international matter as social problems become more complex, poverty increases, community life worsens. This demands that the nature of social work be clarified. Will this lead to further radicalization?

Radical social work from the 1970s evolved into critical social work, currently termed 'structural social work' and/or antioppressive practice. This article sketches a short history of radical social work practice and theory, focusing on Flanders and the Netherlands. A survey of social work educators and practice-oriented research illustrate where radical social work's core might lie.

Introduction

Increasing unemployment, migration, and bank crises, have characterized welfare states over the past decades. When searching for answers within a neoliberal and neocapitalist context, social work can play a maintenance or critical role (Dominelli, 2010). Given this history, does the practice of social work offer answers for a social justice society? Social work's international bodies suggest that the mission of social work is social change, solving difficult social problems and enhancing peoples' well-being (IFSW and IASSW, 2004). Does social work neglect its mission by identifying itself too much with psychotherapy? Sometimes social workers find their clients or participants difficult and marginalized. On whose side are they? Do they spontaneously choose the side of oppressed, disadvantaged, and vulnerable people? Do they recognize the barriers in peoples' lives or do they see people as impeding their own self-empowerment? Are organizations, workers, and policymakers held accountable? Is working on social justice, equality, and emancipation at the foreground of reclaiming the radical social work, a tradition?

This article develops another definition of social work by considering how radical social work is described in the literature and what its traditions are. An exploration of the existing vision of social work was conducted by asking questions of methodology tutors and social workers. Interviews and interactions with the focus groups were conducted in order to explore the meaning and values that tutors, social workers, service users and managers assigned to social work. These results ground my description of radical social work and how social work is practiced, and help social workers and tutors to specify the heart and identity of social work.

Social Work and Radical Social Work

Social work is anchored in society. The profession of social workers has provided professional answers to requests for help. Berteke Waaldijk (1996) argues that from the beginning of the professionalization of social work, social workers realized that the profession constantly needed to legitimize itself according to the rapidly changing contexts in which it operated. Consequently, social workers have to immerse themselves thoroughly in the broader contexts of the profession and appreciate such influences on their practice. Van Riet (2006) states that, if they fail to do so, practitioners would become victims similar to the people with whom they work when providing care and enhancing well-being. But what is social work about?

In describing social work, I look into its history to determine why it came into existence. "Social work is a fluid entity – it grows, develops and changes" (Thompson, 2005: 16). Besides its history, the objectives or purposes of social work, i.e., why it exists, needs clarification. The question, 'What is social work for?' is highly contested. Several authors have developed different typologies or classification systems for social work theory. This discussion is, however, limited to the difference between 'social work and social order' and 'social work and social change' (Thompson, 2005: 22). Payne (2005) describes the gap between liberal and critical visions. Professional social work is a classical analysis of social work as a discourse among three aspects of practice: social order, therapy, and transformation (Dominelli, 1997; Payne, 2006). The theoretical debate continues to be held from among these three visions of social work, linked to liberal, humanistic and critical visions of welfare and humanity (Howe, 2008). Critical and radical theories of social work practice stem from Marxist social theories. First, these theories are transformational and aim for social change. More specifically, they reject capitalist, neoliberal and rational approaches to managing the economy because of contradictions between those who own/manage the means of production and the workers. Radical and critical theories stress the structural elements of social problems and focus on inequality and oppression. These theories are emancipatory or committed to the liberation of peoples from the barriers imposed by the existing social order. Radical and critical practices try to *raise awareness* about social injustice, political action to enhance social change (Dominelli, 2002b). Raising awareness helps to battle cultural hegemony through which powerful people uphold the existing social order and take advantage of people's social and cultural convictions through the media and education (Payne, 2005).

However, radical social work has never been a dominant tendency in social work. According to Midgley (2001), from the beginning of social work practice, three (sometimes overlapping) approaches could be distinguished: the (traditional)

'remedial social work' which has been the approach most often used historically and has an individual focus; 'developmental social work' which rose as a reaction on remedial work and focuses on processes of economical and social development; and (progressive) 'activist social work,' better known as radical, structural, or antioppressive social work (Midgley, 2001). Radical work is hidden in the history of social work. Initially, the radical approaches criticized the traditional social work for its focus on individual methods of helping and individualized notions of personal problems (Leonard, 1975; Fook, 2002). In Flanders, this criticism appeared when social casework failed to promote individual development and the structural causes and effects of problems gave way to collective interventions through community work (Herman, 1996). Social workers reacted with alternative small social services agencies that integrated social care, education, or therapeutic consciousness and social action with political aspects (De Turck, 1978). This political social work was based on rights and developed into a rights discourse. During recent decades, this discourse has oscillated between the political climate and social work (Driessens and Geldof, 2009). The task of social work is to support oppressed people, groups, and communities by challenging systematic discrimination and inequality (Leonard, 1975; Corrigan and Leonard, 1978; Dominelli, 1988, 1996; Mullaly, 1997, 2001; Thompson, 2005; Verzelen, 2005; Driessens and Geldof, 2009).

Hence, international, and to some extent Flemish/Dutch, literature shows that radical social work emphasized the heart of social work. Its theories can be called radical because they describe how social inequality and oppression and dominant power relations can be changed through raising consciousness and social action. Various authors define radical or structural or critical social work in their own way, based on the radical tradition (Bailey and Brake, 1975; Galper, 1975; Throssell, 1975; Leonard, 1975; Corrigan and Leonard, 1978; Howe, 1994; Dominelli, 1988; Dominelli and McLeod, 1989; Dominelli, 1996, 2002a,b; Fook, 1996, 2002; Mullaly, 2001; Ferguson, 2008). An examination of these traditions makes substantive points about the root of social work. With the focus on inequality and oppression, the political and ethical or normative aspect as the core business of social work is proposed.

Traditions from the 1970s

From the 1970s, radical social work or the 'old' radical social work approach focused mainly on Marxist social theories. It criticized the capitalist system and traditional social work and launched a call for changes that enabled social work to change capitalist society, favor the working class and eliminate its pathologizing approach to individuals needing help. Social work practice, i.e., casework, was criticized because of its individual approach perpetuating the social order, to promote instead, community work as a collective approach (Bailey and Brake, 1975; Dominelli, 1990; Fook, 2002; Ferguson, 2008). The aim was not to eliminate casework, but to raise awareness of its deficit approach to service users (Dominelli, 1988). This awareness and the simultaneous coming together of critical social workers, service users, students, and academics was of vital importance. Within the current or 'new' radical social work, sociocritical theories provide a theoretical frame alongside social and sociological theories. Initially, critical theory was a tradition of thinking ('theorizing') referring to Marx and Hegel, while emancipating itself from this tradition. A core principle of critical theory is analyzing society holistically (relationships and systems) rather than as a collection of individuals. It focuses on structural power relations and models of domination while seeking structural change, and encouraging positive ideals (Laermans, 2009). Within this tradition dominant power relations are analyzed, giving social workers and clients/service users the opportunity to develop critical awareness for undertaking critical social work practice (Mullaly, 2001; Fook, 2002; Ferguson, 2008).

Radical social work since the 1970s has been a strong movement. Rather than disappearing, it finds roots in emancipatory social movements concerning women's rights and the oppression of specific social groups on the basis of 'race,' ethnicity, disabilities, age, and sexual orientation (Dominelli, 2002c). Radical Marxist theories of social work practice were critiqued for not having models for practice (Dominelli and McLeod, 1989). Neoliberalism from the 1990s marked a shift in the political climate and required engagement with professionalization and managerialism. Instead of equality and solidarity, contemporary politics focus on the strength of the individual and the idea of the free market (Hoogerwerf, 2001) and impacts adversely on what social workers can do (Dominelli, 1996, 1997). Also psychosocial discourses from the 1970s alongside Rogers' client-centered practice continue to promote human potential and growth (Payne, 2005).

In the first decade of the twenty-first century, radical or critical social work prevails again. Environmental- and climate movements, as well as anticapitalist, antiglobalist, and antiwar movements predominate, given the global crises (Dominelli, 2009, 2012; Ferguson, 2008). Under the influence of postmodernism and social constructionism of the 1990s, critical ideas have prospered and led to the reformulation of Marxist social work, utilizing critical theories of society, and the practice of empowerment and advocacy (Payne, 2005). A keystone of the radical, structural or critical approach is the focus on social structures and 'not blaming the individual victim' for problems (Fook, 2002). These approaches do not take the social order for granted.

Radical social work, the critical movement of social workers in the 1970s, occurred rather moderately in Flanders. Most social workers focused more on the external and societal causes of the problems their clients faced. Accordingly, social workers engaged in the battle to tackle and change these societal causes, rather than accept that problems would be solved on an individual level (Verzelen, 2005). Societal critiques illustrate the highly unequal distribution of resources and chances to purchase economic, political and cultural goods (income, power, knowledge, status). These critique produced alternative and politicized social work, social action, education (awareness), and social work. Politicized work is primarily structural and environmentally based, and entails a collectivization of the issues instead of their individualization. Characteristic of this perspective is social workers' preference for client choice and their activation through externalizing societal and social problems instead of internalizing them (Snellen, 2002). The dominant attitude of social workers is that they show solidarity

with the client, that they struggle against the internalization of social problems, and that they fight structural causes, not least, within their own institutions. The conflict within their own social work organizations is addressed by paying attention to the role their superiors/managers have in limiting clients in the interest of reproducing their power as owners and/or managers siding with the ruling interests (Verzelen, 2005).

The emancipatory approach takes this societal critique a step further. Society is not just a combination of external problem-causing factors. It is also within the person, a factor of one's identity. This identity is reproduced by the processes of socialization and patterns of human interaction. Discipline and the power to discipline are general societal phenomena which occur both within societal institutions (state, capitalism) and interactions occurring on the microlevel (Snellen, 2002). According to Snellen (2002), emancipatory work (cf the empowerment-approach from the 1990s), aims to help people to control their own lives, discover their own possibilities, have their voices heard, and fight situations of inequality and oppression. When taking on the problem/situation, their focus lies with the client, as an involved 'expert' actor. Now, more than ever, social workers have to immerse themselves in the causes of people's problems, working informally and being with or deeply involved in poor people's situations, and acting to improve situations and make their work matter (Van Riet and Wouter, 2002).

Lost in the 1990s

Critical trends connect social work with the need for change in social and institutional relations in society and illustrate how social work too easily withdraws into the microlevel (De Bie and van Ewijk, 2008). From the roaring 1960s to the 1980s, the critical social work movement continued its lead on the internal critique of the psychologization of social problems and the external one that ignored the politicization of the profession (Herman, 2001). Verzelen (2005) argued that social work discourses traverse two traditional forces, going back and forth between the emphasis on individual responsibility and that of societal and social environmental factors.

Simultaneously, through extensive professionalization and institutionalization, social work made itself rather immobile and impotent. Van Riet and Wouter (2002) uses Procrustes' metaphor (literally the stretcher): the needy are stretched or customized to the supply of aid. With their supply and expertise, social workers preserve their own market and deprive clients of their own capabilities (Achterhuis, 1980). This message brings great uncertainty and reticence within social work and helps legitimize government cuts. The neoliberal climate of the 1980s and 1990s, led to marketization, commercialization, and the withdrawal of government provisions, while postmodernism challenged the prevailing grand narratives and ideologies that resulted in deprofessionalization (Herman, 2001). Neoliberal politics initiated the transformation from a welfare state to an activation welfare state (De Bie and van Ewijk, 2008) whereby individuals were held accountable for meeting their own needs. These initiatives prioritized individual progress over collective progress. The liberal injunction that each individual is responsible for him/herself is based on transference of free market principles to human relations (Hoogerwerf, 2001). The tendency to commercialize services increasingly leads to a certain 'contractualization' of relationships: contracts instead of contacts. Professionalism increasingly stands for rationality and detachment, a new business-like character in which well-organized activities preferably yielding quantifiable outcomes. Notions of attention, being with, equality, seem old-fashioned and unprofessional because outcomes are wanted and only talking is not expected from professional social workers (Jacobs and Van Doorslaer, 2000).

Apart from the neoliberal approach, also called neoconservatism, Reaganomics, or Thatcherism, postmodernism played an important role, rejecting the 'grand narratives' for paying limited attention to equality and emphasizing instead the diversity of people and cultures. The welfare issues of the most vulnerable are deemed safety problems. Hence, the care of vulnerable groups has shifted to the fear of a new 'underclass,' which is a risk for the middle and higher classes (Wacquant, 2012). Risk images are dictated by fear of the unknown, unfamiliar, and unconventional. Negative solidarity and notions such as risk, harm, and mostly 'nuisance' prevail. As a reaction, the demand for safety, security, and control increases. This is where a paradox originates – the tendency to consider danger as manageable risk, makes people see more danger, at which point feelings of fear and insecurity will increase even more. Fears are dramatized, due to the way the media and politics respond to this matter. Consequently, more means of social control arise with the aim of restricting feelings of fear and preventing crime. This phenomenon is not new. Scientific research plays a greater role and empirical research on crime increasingly acts as a scientific base for policies on criminality. Along with new technological possibilities this leads to different interventions.

The government increasingly focuses on 'controlling risks and evil.' A new sort of state is created, a new kind of governance (van Swaaningen, 2001). The government rejects certain tasks and is led by experts (the power of consultants), entrepreneurs (the power of the market), and interest groups (the power of the lobby). Foucault (1991) discusses the 'microphysics of power': power relations are not presented in a pyramid structure with a ruler or monarch giving top-down orders. Power is exercised on different levels and places in society and stems from a network of private and public bodies without absolute power, but with many different powers, based on professional knowledge and the resulting relations of authority (van Swaaningen, 2001).

This 'remote administration,' as Foucault puts it, implies that the government draws policies and that the precision and implementation of these policies is left to third parties in the private sector. The withdrawing government has a different role, a different character, and is rather an enterprising government. Governance is a question of business by making use of tactics rather than laws, and even the laws are used as tactics (Foucault, 1991). Due to the withdrawal of government, a democratic shortage can occur. A radical depoliticization of society takes place: politics becomes an arena parallel to other arenas such as economy, law, and art (Visker, 2005). Politics is more about technical and governmental guidance of processes (resources) and is less based on substantive arguments and fundamental choices or deliberation (goals) (van Swaaningen, 2001).

Reclaiming the Twenty-First Century

Social work has become too much an 'executor' and evaluator of risks, thereby falling into bureaucratic routine and marginalization (De Bie and van Ewijk, 2008). Professionals have been hiding behind office windows and procedures and have increasingly isolated themselves from people's living environments (Van der lans, 2010). However, there is another aspect: 'corrective external influences,' such as the development of user movements and experiential knowledge of poverty reduction, where approaches of living environment and presence, critique bureaucratic welfare work (Verzelen, 2005).

Radical social works connects a structural analysis of individual problems with the ethical imperative to act. During past decades, this combination has been attractive to social workers, who accept that social justice and equality are a central part of social work (Dominelli, 1997; Powell in Ferguson, 2008: 96). Social workers should report more on the impact of (neoliberal capitalist) policy on their client's lives. Social workers can make the difference and play a role in securing equality and justice in society (Bailey and Brake, 1975; Galper, 1975; Throssell, 1975; Dominelli, 1990, 2009; Thompson, 2005; Ferguson, 2008). They can formulate an ethical answer, based on a critical analysis of the political context in which social work is situated. It is important that social workers unite to develop a new vision, paradigm or ideology for practice (Mullaly, 2001).

The current international definition of social work states that principles of human rights and social justice are fundamental to practice and that social work targets social change, problem solving in interpersonal relations and empowerment and freedom of people, considering their well-being (IFSW and IASSW, 2004). This could indicate a positive attitude for a transformational socialist collectivist vision, but with the focus on the social and political position of service users/clients (Payne, 2005). Social work as emancipatory practice is person-centered, empowering, and critical of power structures and systems of resource distribution that undermine the well-being of both the many and the individual (Dominelli, 2009: 2). Working on social change is trying to change the negative and destructive aspects of society, such as discrimination and oppression. Working on social change does not mean that social stability is not important. Social work should question which aspects should be retained. Thompson (2005) argues that a 'realistic' vision of social work focuses on social stability and social change. Providing social stability strengthens those aspects that promote individual and social well-being/prosperity. Social workers address social problems that have their roots in society. The stress on the social dimension of problems would pave the way for social work to promote social change again (Jordan, 2006; Roose, 2006).

Theoretical Evolution

Theory-development in Flanders is reflected in limited publications. Some specific theoretical bases for Flemish social work stand out (Verzelen, 2005). During the period 1960–80, human and social sciences were evolving and adult-learning about change and expertise began to fill the gap of the missing basic science for social work (Verzelen, 2005). This 'new' science feeds welfare work with an individualistic approach alongside sociocultural work with its commitment to changing society. For this approach, Freire's work (1972) leads on adult-learning theories. Freire directly influenced Flemish sociocultural work in general, and literacy work in the 1980s in particular (Verzelen, 2005). Freire connected the living environment of his participants to their thinking about inequalities and injustice in society (Verschelden and De Droogh, 2009). Indirectly, he influenced social work more broadly, because Piet Reckman and Bert De Turck politicized social work's development within welfare and sociocultural work.

The sociocritical approach is also fed by sociological theories, i.e., 'critical theory,' mainly from the Frankfurt School including Marcuse, Fromm, and Habermas. With a model of communicative dialogue, Habermas presents a way for reaching binding (ethical) conclusions (Verbruggen, 2007). Both Freire's (1972) thinking and critical theory helped realize the connection between engaged emancipation perspectives and techniques of support (Verzelen, 2005).

Finally, other theories for mention regard the rise of target group approaches in the 1990s and include theories on street outreach work or Baart's (2006) presence theory. These theories consider welfare work and poverty, i.e., custom work, connective strength, and empowerment (tailoring care) (Van Regenmortel, 2002), and become a binding force in poverty (Driessens and Van Regenmortel, 2006). Simultaneously, Boszormenyi-Nagy and Krasner's (1994) and Boszormenyi-Nagy's (2000) contextual approaches are, together with the systems approach, the most important source for methodological ideas for current welfare workers (Verzelen, 2005).

Even though psychotherapy's influence on social work is more extensive in the United States than in the Netherlands and Flanders, social work must realize that it will neglect its mission by identifying too much with psychotherapy (Van Riet, 2006). Because social workers are the closest to social problems, they also have a public role and they should present themselves socially, given growing poverty, unemployment, social inequality, and extreme exclusion and stigmatization (Driessens and Geldof, 2009). Hence, the tension of individual and structural change remains relevant in the twenty-first century. Also, the international definition of social work links individual and structural work with one another to promote social change. Different perspectives or theories stipulate whether social workers think and act from an individual or institutional responsibility perspective (Van Regenmortel, 2002; Driessens and Geldof, 2009).

Exploring Social Work Practice

Nowadays, the debate on radical or structural social work is also being held in the field. Regarding practice-oriented research by KH Leuven and KU Leuven (Bloemen, 2012), a survey has been conducted to address actual needs expressed by social work organizations willing to work structurally. Participants from various organizations expressed concerns about this topic to the advisory committee for this research project. Both regional and Flemish partners were represented on this committee. Its members were from a local social services

agency in Genk (OCMW), an organisation supporting experts by experience in Leuven (Leren Ondernemen vzw), a center for general welfare in Leuven (CAW), street outreach work in Flanders (Vlastrov), community development in Flanders (Samenlevingsopbouw), and youth work in Flanders (Uit de Marge). During this research the education institution and field closely collaborated alongside the students taking a Masters in Social Work degrees (KU Leuven).

Interviews had been conducted and three focus groups were constituted. The members of these focus groups were specifically chosen for their experience in social work. Participants defined structural work as caring (primary) and political (secondary). It does not exclude individual work, but combines individual and collective work (group-centered, project-based, community-centered). Structural work is a laborious effort about major, long-term changes as well as small, short-term activities and is rooted in people and anchored in society. It centers people in different ways by initiating policy changes from the bottom up. Instead of guiding people, it creates space to develop new structures. A development of transparent organizational structures and communication channels seem crucial to working structurally. Advocacy groups can be mandated to undertake such work, given their independence and organizational structure. Networking is crucial for structural work and making links with movements such as professional associations and civil society. Solidarity is crucial in making contact with people, to stand among them and be on the same side of the barricade.

Strikingly, social workers are hindered to do their work given the absence of space for critique and the lack of an ideological framework. More specifically, the lack of vision and ideology and the lack of sociocritical analysis appear to be a great obstruction. Being able to analyze is a must and a starting point for critical social work. Insight into politics, mechanisms of exclusion, policymaking, law, and their implementation are imperative to work transformationally and emancipatorily. A critical–ideological and collective framework as a base for action is meaningful and needs to be acquired by social workers. Dealing constructively with anger and completely supporting the goal of equality are mentioned as social work drivers.

During their education, social workers have to be enabled to critique society, develop a critical attitude and insights into the backgrounds and underlying paradigms of societal phenomena (Cuyvers, 2009). Bloemen (2010) conducted interviews to explore ideas about radical social work and the profession of social work. Four Flemish polytechnic universities were included in the study. Analysis of the 18 in-depth interviews highlighted the importance of social workers' (critical) reflective capacity and vision development; the challenges of increasing collaboration between education and field; the lack of social work influence on the structural societal level; and the demand for unity among social workers. Most respondents name the capacity of reflection a skill which students acquire during their social work education, alongside communication skills. They think that the development of vision is a task for the School to provide frameworks that promote thinking and gaining insights into society. Respondents generally did not specify these frameworks. Within 'new' radical social work, critical theories are put forward (alongside sociological theories) as theoretical frameworks because they analyze society as a whole, taking power relations into account.

Most respondents answered positively and convincingly the question of whether social work can influence social change. In microlevel or individual contact with people, social workers definitely make a difference, according to the methodology tutors. Some respondents pointed out that influencing the meso- or organizational level can be taught. Social work indicates that by developing activities of individual and collective resilience, social workers can promote change. Thus, social change can be initiated by questioning the organization. The policy or macrolevel was unanimously considered as the level on which too little action took place. Social work can steadily evolve into becoming a codesigner of social politics and social policy, by emphasizing the link between social work and the basic objectives of social justice and equality. This approach considers social work as having the expertise to make critical connections between individual situations and societal developments (Driessens and Geldof, 2009). However, the question arises as to how this is to be put into practice?

Social Work Making Radical Progress?

The information this research project provided shows that social work practice and theory developments influence one another. From its beginning onward, social work has been philanthropic, caring for social stability. It has also focused on social change to stress the structural elements of social problems and inequality and oppression. Social work is emancipatory or, committed to removing the barriers that limit peoples' aspirations within the existing social order. Social inequality, oppression, and dominant power relations can be changed by raising consciousness and social action. Social workers are aware of the influence of the broader context and hegemony of neoliberalism and capitalism. The analyses of dominant power relations gives social workers and clients/service users the opportunity to develop critical awareness as a base for a critical social work practice (Fook, 2002; Ferguson, 2008; Mullaly, 2001).

During recent years, there has been an increase of social movements identifying capitalism as the culprit of poverty and environmental destruction (Dominelli, 2012). According to Mullaly (2001) structural social work can support social movements that promote social transformation. By stressing the connection between social work and basic goals such as social justice and equality, social work will be able to become a codesigner of social politics and social policy. This approach considers social work as having the expertise to link individual situations to societal developments (De Bie and van Ewijk, 2008).

The dominant attitudes among social workers in this project were that of showing solidarity with the client, and battled against the internalization of social problems, and tackled structural causes, not least within their own institutions. Both within and outside of their organizations and systems, social workers can engage in and encourage social change. It is imperative for social workers to have a clear view

on the immediate, varied, and changing situations that people live within from day to day (Saleebey, 2006). A societal viewpoint implies that the engagement of social work is not limited to microsituations, but extended through a broader societal and historical analysis, conducted by critical social workers. Social work radicals cannot simply discover and analyze the causes of oppression or injustice. The next stage is to transform their insights into immediate social action (Reisch and Andrews, 2001). This alternative approach is something that clients and practitioners do together, forming alliances with each other as necessary (Dominelli, 2004).

Radio as a Medium

Abstract

Due to its mobility and low cost, radio is the most widely used electronic medium of communication on the globe. Although public monopoly broadcasting dominated until the 1980s, US-based commercial broadcasting was a global force beginning in the 1930s. Radio played a key role in promoting national political and cultural integration under both models. By the late 1980s, most of the world's radio systems faced liberalization of some kind, although the Arab world held out until the 2010s. A global community radio movement emerged in the 1980s and expanded in the 2000s, nurtured by democratization struggles.

Radio, the transmission of sound via electromagnetic waves, is the most widely used electronic means of communication on the globe. It is second only to spoken language and nonverbal interaction as a medium of human communication. Despite the broad reach of television and the growing role of cable and Internet, radio remains an important arena of cultural expression, commerce, politics, and education in advanced capitalist countries. In many developing countries, including most of Africa, much of Asia and the Middle East, and parts of Latin America, Eastern Europe, and Oceania, radio continues to be the primary means of mass communication. Due to its mobility, low cost, and flexibility, radio is one of the fastest growing media of communication worldwide.

Although radio has a variety of scientific and commercial applications as a *technology of radio wave transmission* (e.g., radio astronomy, radiotelegraphy, radiotelephony), as a *social medium* radio has been configured principally as a means of point-to-mass communication or broadcasting. Two broad models of radio broadcasting emerged during the first half of the twentieth century: commercial broadcasting and public monopoly broadcasting. While both models defined the radio wave spectrum as a public resource or good, they differed on whether the spectrum should be exploited by competing private entities for profit or developed by a single public entity as a nonprofit service. During the last quarter of the twentieth century both commercial broadcasters and community-based nonprofit broadcasters challenged the public monopoly model and launched new and hybrid broadcasting forms. The following article examines the cultural, technological, economic, and political factors that shaped radio as a social medium of broadcasting.

Technology and Cultural Form

Radio is comprised of a dynamic sound technology wedded to a flexible yet resilient set of cultural practices. This combination of technological and cultural factors both enables and constrains radio as a medium. Radio production, for example, is shaped by the capacities of the technology (real-time, sound-only) as well as the forms of expression that have been adapted to the medium over time (program genres, formats, and presentation styles). Radio reception is likewise constrained. For example, a portable, personal radio differs from a console radio in both its technological configuration and in the cultural assumptions that shape its use (mobile-individualized listening vs situated-shared listening). This interaction of technology and culture shapes not only the form and content of the radio medium, but radio's relationship to time, space, community, and identity.

In this sense, a defining feature of radio as a technology and cultural form is its conflicted relationship to modernity. On the one hand, radio broadcasting represents a heightened sense of movement toward modernity; that is, movement toward a condition in which human social relations are increasingly abstract, individualized, and future-directed. To the extent that radio is understood to speed up processes of social progress and development (through, for example, the diffusion of innovations) the medium evokes a sense of 'hypermodernity.' On the other hand, radio provides a means of resisting or allaying the impact of increased mobility and rationalization in social life. To the extent that radio is used as a tool for building intimacy and community in an individuated and changeable modern world, broadcasting practices are 'antimodern.'

Radio broadcasting both reflects and constitutes uniquely modern forms of social organization. It works to integrate and coordinate an increasingly mobile, dispersed, and complex society, at the same time that it promotes the privatization of social life. The simultaneous access of vast numbers of isolated listeners to a single radio content creates a virtual common space that tends to become coterminous with the nation (due, in part, to government regulation and commercial market formation). In this way, radio, like print and cinema, acts as a medium for the "community in anonymity which is the hallmark of modern nations" (Anderson, 1991: 36).

At the same time, however, radio voices have a materiality that reproduces the immediate, tactile quality of primary orality in a number of ways. Roland Barthes's concept of the 'grain' of the voice is helpful in characterizing the somatic presence of radio voices. Barthes (1990) describes the grain as "the body in the voice as it sings"; that is, the listener's sense of the physical presence of the performer in the sound of his or her voice (299). Walter Ong (2012) argues that radio talk has the same ability as oral speech to envelope and immerse listeners, uniting the audience "with themselves and with the speaker" (73). Indeed, broadcasters actively work to re-create

the sociability and interactivity of oral settings by developing intimate, chatty forms of radio talk. In this way, radio gives listeners a sense of continuity with older forms of intimacy and community at the same time that it enables distinctly modern forms of social life.

History and Political Economy

Radio has historically been deployed by a range of political and economic institutions largely within the bounds of the nation-state. During the last two decades of the twentieth century radio changed from a predominantly public service medium to an eminently commercial one. To understand the meaning of this global transformation it is necessary to investigate the social forces that guided and shaped radio broadcasting beginning in the 1920s. Among the most important influences on the medium have been national and transnational communication corporations, the state (nationalist and expansionist) and community groups.

Beginnings: The 1920s and 1930s

Radio expanded from a means of point-to-point communication to a medium of point-to-mass communication, or broadcasting, during the 1920s and 1930s. The rise of broadcasting was both shaped by and reflective of larger political and economic changes in the first quarter of the twentieth century, including the rise of transnational communication corporations following World War I (e.g., Philips, RCA, Telefunken), the growth of product marketing, increased trade in cultural goods (e.g., film and recorded music) and the escalation of both nationalism and international expansion. Technological developments including voice broadcasting (replacing Morse code) and high-power radio transmissions were also necessary ingredients for broadcasting.

Approaching the medium as a strategic communication technology, scarce resource and tool for national integration, central governments began asserting control over the radio spectrum in the 1910s and 1920s. In part, this followed the pattern established by state intervention in telegraph and telephone development. As a U.S. Commerce Department publication lamented, "When the social possibilities of broadcasting became apparent many countries determined upon maintaining it as a public utility, particularly those where government ownership of communication services had previously been the rule" (Radio Markets, 1932: 2). Even in the United States, however, the central government claimed radio as a public resource and used regulatory powers to promote a national broadcasting system with citizenship and public service requirements for broadcasters. These regulations, codified in the 1927 Radio Act and again in the Communications Act of 1934, granted concessions or licenses for commercial broadcasting and actively encouraged the development of commercial networks on a national scale.

Radio was shaped by a climate of intense nationalism and international expansion. In industrialized countries radio was viewed as a means of consolidating the nation as both market and polity, strengthening ties with colonies and dependencies and opening foreign markets. For example, the British Broadcasting Corporation (BBC) began its Empire Service in 1932, while the Japanese government established broadcasting stations in occupied territories in both Korea and China. The U.S. media corporations such as the Radio Corporation of America, General Electric, and Westinghouse financed broadcasting stations in foreign markets in order to promote the sale of radio receivers (e.g., Latin America). In less-industrialized countries and colonial territories broadcasting rarely reached beyond a few major cities and was often limited to the interests of colonial governments (e.g., Hong Kong, Kenya).

In postrevolutionary societies such as Mexico and Soviet Russia, as well as fascist countries like Germany and Italy, the state turned to radio as a tool for building political solidarity and cultural identity through official broadcasting projects and the distribution of radio sets for both public and in-home listening. In Nazi Germany inexpensive radio sets known as the 'People's Wireless' or 'Goebbel's Lips' allowed listeners to tune in Adolf Hitler's speeches but blocked the reception of foreign stations (Euromedia, 1997: 79). In almost all independent countries radio developed within a nationalistic framework: broadcasters were required to be citizens transmitting from national soil, the state was given special access to the medium on the grounds of national interest and security, and content was frequently regulated to promote and 'improve' the national culture (e.g., language and music requirements).

Although radio broadcasting took many different forms, two broad types of radio organization – commercial broadcasting and public monopoly broadcasting – emerged during this period. In the commercial model, radio programs were designed to attract large audiences that could be sold to consumer product advertisers through program sponsorship or 'spot' advertisements. This model predominated only in the United States and Latin America, although Canada, Australia, and New Zealand had significant commercial radio sectors and small pockets of commercial radio existed elsewhere. In France and Luxembourg, for example, private broadcasters transmitted commercial programs in direct competition with the BBC (e.g., Radio Luxembourg, Radio Normandie). In the vast majority of countries and occupied territories radio was a public monopoly (or modified monopoly) financed by government subsidy or receiver license fees and subject to varying degrees of government control. These two general models yielded different geographies of broadcasting: whereas public monopolies tended to produce a small number of stations serving the national community (with limited regional or local service), commercial systems tended to generate a large number of stations serving the local community. With the rise of national networks, however, local commercial affiliates developed a strong national orientation.

Only countries in North America and Western Europe approached universal radio access by the end of the 1930s when, for example, about 75% of the British population had radios. One of the most influential broadcasts of the era, Franklin Roosevelt's first Fireside Chat of 18 March 1933, was heard by an estimated audience of 60 million (out of a total population of about 120 million). Urban and industrializing areas of Latin America, Oceania, and Asia, including the Soviet Union, had small but growing numbers of radio listeners. Rural parts of these regions, along with most of Africa and the Middle East, had negligible radio listenership.

Takeoffs and Transitions: The 1940s and 1950s

World War II had a major impact on radio organization, content, and listenership. Timely broadcasts of news and information greatly increased the utility of the medium, promoted frequent listening, and raised demand for radio sets both during and after the war. Radio listening grew even in countries where most people could not afford radio sets (e.g., Egypt) "because merchants or owners of coffee shops would have a set to attract customers" (Dabbous, 1994: 65). The role of the central state in broadcasting also increased significantly on both the domestic and international fronts. At home, the state took an interest in the security and efficiency of the radio system. Official reports and government-sponsored programs proliferated on both public monopoly and commercial radio stations. In some cases (e.g., Vichy France) the state used the wartime emergency to prohibit private broadcasting and institute a public monopoly system.

International broadcasting was exploited by all of the belligerents during the war, largely in response to Italy and Germany who invested heavily in short-wave broadcasting. The BBC, for example, became the medium for Charles de Gaulle's appeals to the French Resistance, beginning with his celebrated broadcast of 18 June 1940. The U.S. government developed international broadcasting projects aimed at Asia, Europe, and Latin America. In the case of Latin America, the U.S. Coordinator of Inter-American Affairs developed a wartime broadcasting offensive that worked to solidify U.S. hegemony in the region while strengthening the cultural influence of U.S. advertisers and a small number of Latin-American broadcasters. In 1948, the Coordinator's radio unit was transferred to the U.S. State Department where it became the Voice of America broadcasting service. By the end of the war, international broadcasting became the provision of the central state.

Radio broadcasting became one of the most important ideological and political tools of the Cold War. Along with international broadcasting, the United States, Soviet Union, and their allies sponsored clandestine radio stations in countries around the world (e.g., Guatemala, Turkey, Yugoslavia). The mobility and low cost of radio, however, also made it a powerful tool for grassroots revolutionary movements in the postwar period. Communist insurgents in China in the late 1940s and revolutionaries in Cuba in the late 1950s used clandestine broadcasting stations to maneuver against their enemies and mobilize popular support. Fidel Castro's Radio Rebelde, for example, became a model of effective clandestine broadcasting for decades to come.

Most of the countries that fought for independence at the end of World War II (e.g., China, India, Indonesia) followed a path similar to earlier post-Revolutionary societies: they established state-directed broadcasting systems that controlled language and content and used the medium for nationalist ends. New governments struggled to improve broadcasting coverage and increase listenership quickly and efficiently. Consequently, broadcasting services were often highly centralized and limited to one or two national services (e.g., the Central People's Broadcasting Station in Beijing, China).

The history of radio in the postwar period was also shaped by the rise of a second broadcasting medium: television. Although television fundamentally transformed radio broadcasting in the United States during this period, television's impact was much more gradual worldwide. Radio remained a public monopoly in most countries and a strong competitor for the national audience. In parts of Europe (e.g., Italy, Norway, Sweden) television failed to reach a majority of the population until the early 1960s and in Latin America the high cost of television guaranteed that radio would continue as the primary mass medium. Indeed, this period can be characterized as a *golden age of radio* in countries with developed broadcasting systems. In Latin America, for example, popular music (e.g., mambos, rancheras, sambas) provided the primary material for broadcasting while the radionovela (drama serial) reached the height of its popularity. In both commercial and public monopoly systems this was an important period of genre formation, with the live production of musical variety programs, comedies, soap operas, novelas, news, and game shows filling the airwaves.

In the United States, radio changed radically beginning in the early 1950s. In order to develop national television networks, broadcasting corporations like the National Broadcasting Company stripped capital, talent, and program genres from radio and ultimately dismantled their national radio networks. Without national network programming, radio stations were forced to reorient their activities to the local and regional level and cultivate new markets (e.g., teenagers, ethnic minorities, and out-of-home listeners). Radio content became increasingly diversified and localized as radio shifted to a repertoire of recorded music supervised by disk jockeys or DJs who advertised products and promoted the radio station. By the late 1950s, stations were catering to narrow market segments with increasingly standardized program formats (e.g., 'beautiful music' and 'top-40').

Overall the early postwar period was marked by two divergent trends in radio broadcasting. While richer Western countries moved away from radio and toward television as the primary broadcast medium, many newly independent, postcolonial countries looked to radio as the primary tool for national communication and unification projects. Although television came to symbolize development, it remained impractical for the vast majority of countries due to high costs and infrastructure limitations. Beginning in the postwar decades, then, a significant divide emerged and grew between countries that saw high levels of television penetration beginning in the second half of the 1950s and those in which radio remained the primary mass medium through the late 1970s and beyond.

Change and Competition: The 1960s and 1970s

Public monopoly broadcasting remained dominant during this period despite technological changes and increasing competition from television. In the countries that emerged from the last major wave of decolonization (e.g., Algeria, Nigeria, Uganda), public monopoly broadcasting with strong government influence was the norm. In their 1975 study, *Broadcasting in the Third World*, Elihu Katz and George Wedell noted the tendency toward government control of radio broadcasting in many developing countries. In the case of

Nigeria, for example, they observed that "The demands of a government needing to assert its authority over a country of 50 million people of diverse ethnic, linguistic, and cultural characteristics, between 70 and 80 percent of whom were illiterate, made closer control of broadcasting inevitable" (83).

At the same time, however, public monopoly broadcasters faced growing criticism for controlling and limiting public information. In India, for example, a 1964 government report noted that "Suspicion of official information has deepened in India because of an incorrect, even improper use of media for personalized publicity and an undue accent on [government] achievements …" (Ninan, 1998: 4). In France, during the political crisis of 1968, listeners turned to commercial radio stations outside of France (the peripheral stations) to hear balanced coverage of events that French radio covered with a pro-government bias. In many countries protests against the public monopoly system were registered in the form of unlicensed, pirate stations operating within the national territory. While some countries managed to stave off reforms, significant liberalization began during this period. For example, Italy legalized private broadcasting in 1976 and Sweden permitted noncommercial 'neighborhood radio' as early as 1978.

During the same period commercial broadcasting (both television and radio) came under attack as a wasteland of low-quality programming that failed to meet basic public needs for information, education, and culture. In the United States, legislators responded with the Public Broadcasting Act of 1967, which created a public corporation that helped to finance educational television as well as National Public Radio, a public service national radio network. In Latin America, where radio became accessible to the majority of the population during this period, most governments either initiated or greatly expanded the use of radio in national education projects (e.g., Brazil, Venezuela). Overall, this period witnessed a sizable growth in educational and nonprofit broadcasting by diverse civic groups, including religious denominations, universities, and other nonprofit organizations.

Although radio listening increased worldwide during this period, the divide between rich and poor countries continued. Radio's growth in the developed world was driven, in part, by innovations such as frequency modulation (FM) broadcasting and transistor radios. While FM radio made high-fidelity broadcasting possible, inexpensive transistor sets increased radio's portability outside of the home and facilitated the expansion of car radio. In the United States, for example, both innovations helped to push the number of radio sets to 1813 per 1000 population by 1975. In the developing world, however, FM expanded much more slowly due to the costs of conversion from amplitude modulation receivers. In addition, although inexpensive transistor sets made radio much more accessible to communities without electricity, the price of batteries remained prohibitively high for many listeners. Thus radio penetration remained relatively low in poorer regions of the world at the end of the decade. Asia and the Middle East, for example, had 62 sets per 1000 population while Africa had 70 sets per 1000 population in 1977 (Katz and Wedell, 1977: 62).

Liberalization, Deregulation, and Consolidation: The 1980s and 1990s

The move to reform public monopoly broadcasting that began in the 1970s grew enormously during the 1980s. Liberalization was a response to a variety of pressures: social pressure to increase political and cultural pluralism over the air, political pressure to reduce public spending (especially during a time of economic crisis) and ideological pressure in favor of free market capitalism. This process was particularly evident in Western Europe, where local noncommercial stations were legalized in the early 1980s, followed by commercial stations in the mid- to late 1980s (e.g., Belgium, Denmark, W. Germany). Although competition was permitted at the local level, in many cases public service radio retained a privileged, monopoly-like position at the national level through the late 1990s (e.g., Britain, Finland).

After the breakup of the Soviet Union and the Eastern Bloc in the late 1980s, most of the world's radio systems faced liberalization of some kind. Much of Eastern Europe became an unregulated market open to competition from North American and European companies (although, in fact, development remained limited due to severe economic dislocation in the region). In Africa most countries opened their radio systems to commercial broadcasting, although commercial development was also highly circumscribed by economic conditions. South Africa, for example, began to liberalize its broadcasting system in the mid-1990s with the privatization of some government-owned stations, licensing of new commercial stations, and the establishment of community broadcasting. Only in the Arab world did monopoly systems remain largely unscathed.

What began as liberalization in the 1980s became a move toward market regulation in the 1990s. As commercial broadcasters grew and faced local competition, they moved toward networking, syndication, and consolidation at a national level. In Sweden, for example, although the Radio Act of 1996 prohibited multiple ownership "all but a few of the more than 90 commercial stations [were] closely integrated into four more or less national networks" (Euromedia, 1997: 218). A similar process took place in France where a political movement in opposition to the public broadcasting monopoly was ultimately exploited by commercial interests. Whereas the 1980s had been dominated by small, activist stations, the 1990s witnessed the "oligopolization of the private radio sector in France" at the hands of professional broadcasting corporations (Kuhn, 1995: 107).

The move toward market regulation also produced oligopoly in the U.S. radio industry. Beginning in the early 1980s, deregulation removed federal content regulations and reduced the limits on cross-ownership of media. With the Telecommunications Act of 1996 all national limits on station ownership were removed, opening the door to a series of mergers and consolidations. By the year 2000 radio broadcasting had moved from monopolistic competition to oligopoly: many major cities had one station owner with 40% of the market and some had two owners with 70% of the market. According to Charles Fairchild (1999) the 1996 deregulation aimed, in part, to make radio competitive with other consolidated media industries, thus preparing the radio system for exploitation by integrated media conglomerates. At

the same time, developments such as Internet radio and digital audio broadcasting provided ideal media platforms for the convergence of recorded music, text, and image through a real-time broadcasting style format.

Radio reached almost every person on the globe by the end of the twentieth century. Radio listening continued to grow in the world's expanding urban areas, primarily in the form of in-car and portable radio listening. Radio listening also grew in rural areas due to electrification projects as well as the development of low-tech, wind-up radio receivers that finally made radio affordable in areas without electricity. Radio's popularity also increased during this period as broadcasters exploited the potential interactivity and intimacy of the medium. Listener-participation talk shows reinvigorated the medium and promoted public discussion of personal topics (especially personal relationships) as well as political issues in countries as different as China, Mexico, and the United States.

In the growing commercial sector, radio stations delivered increasingly standardized program formats to targeted market segments. Format-specific radio chains developed a 'brand value' or 'lifestyle statement' that could be "applied profitably to other aspects of their listeners' lives," including other forms of media consumption (Hendy, 2000: 47). Convergence and conglomeration in radio and related media industries (recorded music, television, Internet), as well as the growth of satellite delivery systems, set the stage for transnational deployment of increasingly 'branded' radio services. Although linguistic diversity and national regulatory policies continued to pose obstacles, regional radio integration was feasible in a few linguistically and economically unified regions (e.g., the Southern Cone of Latin America and the European Economic Community).

In contrast, the last decade of the twentieth century was also a boom period for decentralized community-based radio broadcasting. Community Radio broadcasting, which emphasized community control and participation, was nurtured by democratization movements around the globe. The World Association of Community Radio Broadcasters provided a venue for the organization and promotion of community radio and lobbied for 'social enterprise' broadcasting as a means of encouraging economically viable community stations. Just such a model of community radio was initiated in South Africa in the second half of the 1990s, where nonprofit community broadcasters were allowed to support themselves through advertising. These community stations, some of which served populations of over 50 000, provided local service where none had existed before and covered events such as the local Truth and Reconciliation hearings. By 2000, despite the vocal protests of the commercial broadcasting industry, even the United States Federal Communication Commission had approved noncommercial low-power FM broadcasting at the community level.

Radio in the First Decades of the Twenty-First Century

Radio's relevance as a cheap, mobile, and 'eyes-free' medium jumped during the first decade of the twenty-first century as a number of crises (natural and human-made) ratcheted up the communication needs of ordinary people. After the Terrorist Attacks of 11 September 2001, Americans turned increasingly to radio for timely international news and talk shows that provided conservative (and for a short-time liberal) interpretations of 9/11 and its aftermath (Sherman, 2005). The Indian Ocean Tsunami in 2004, Hurricane Katrina in 2005, and numerous large-scale disasters across the globe in the first and second decades of the millennium demonstrated the importance of radio broadcasting as a means of information sharing and logistical coordination at the local, regional, and national levels.

Such emergency conditions, combined with broader trends toward economic liberalization and social democratization, sped the development of community radio on a global scale. Although community broadcasters still faced political and economic barriers – and at times violent opposition – under certain regimes, the sector grew in the 2000s both in terms of the number of community stations broadcasting and the number of countries that legalized the service (Buckley, 2008). The role of community radio in the protests of 2010–11 that came to be known as the 'Arab Spring' has yet to be thoroughly documented, and has been largely overshadowed by the focus on digital and social media. There is no doubt, however, that community radio has expanded, and will continue to expand, in the Arab world in the 2010s. Research will be needed to explore the interplay of traditional broadcast and new digital media in the context of societies undergoing rapid political and social change.

Despite increasing competition from a range of digital media platforms, U.S. commercial radio grew in the 2000s and promised continued growth in the 2010s. One forecaster attributed this growth to national advertisers' recognition of the continued relevance of radio, particularly in urban markets, and radio stations' aggressive pursuit of online advertising revenues (BIA/Kelsey, 2011). Although the future of traditional commercial radio remains uncertain, listeners continue to tune in to its national, regional, and local content, and its format of mass intimacy and anonymous interactivity.

Abstract

Random assignment of units to treatment/control groups allows researchers to make the strongest possible causal connection between the treatment and observed outcomes. This article considers the way in which random assignment is implemented in educational and social field settings. Topics include evidence about the widespread acceptance of randomized experiments, the purpose of random assignment, common objections to randomized studies, conditions that make program implementers more likely to accept random assignment, methods of successfully implementing random assignment, and how to preserve randomization once it has been achieved.

Widespread Acceptance of Random Assignment

The last three decades of the twentieth century have seen widespread acceptance of random assignment as an important aspect of high-quality research studies designed to test the effectiveness of interventions. In the 1970s and 1980s, proponents of randomized designs for studying program impacts began to assemble a literature attesting to their feasibility and frequent use (Boruch, 1974; Boruch et al., 1978; Boruch and Wothke, 1985). By the 1990s, randomized experiments in the social sciences had become so numerous that Greenberg and Shroder (1997) prepared a 500-page compendium of recent experiments in various content areas. The US Congress now routinely specifies that random assignment be used in studies of the effectiveness of federally funded programs, and recently called for a random assignment study of Head Start, America's flagship social program for disadvantaged children (Advisory Committee on Head Start Research and Evaluation, 1999).

Randomized experiments have limitations as research vehicles (see Cook and Campbell, 1979 for a discussion of the strengths and weaknesses of randomized experiments), and they are not universally accepted as the best way to learn about program effectiveness. One sector of the evaluation community espouses the virtues of qualitative research in place of randomized experiments and other quantitative approaches (e.g., Guba and Lincoln, 1982), while another sector is more interested in issues of generalizability than internal validity (e.g., Cronbach, 1982; Heckman and Smith, 1995). Cook (1999) has written about the antirandom assignment culture that exists in American schools of education. Still, there is no denying that American society relies heavily on randomized experiments as one source of information about the effectiveness of social programs (St. Pierre and Puma, 2000).

The Purpose of Random Assignment

As long as researchers take the time to explain the strengths and weaknesses of random assignment studies, those who commonly question experiments are easily able to understand the rationale underlying random assignment. Perhaps most helpful is the argument that random assignment is a special purpose tool, and while it is good only for one purpose, for making causal inferences, it is far better for that purpose than any alternative. As a special purpose tool, random assignment has many limitations. For example, it does not assure group comparability over time (attrition from the evaluation sample may result in nonrandom analytic groups), it cannot ensure that subjects remain in the intervention being studied (with or without random assignment, interventions may incur high dropout rates), and it does not help with issues of generalizability (a one-site random assignment study is no more generalizable than a one-site quasiexperiment). Cook and Campbell (1979) stated it clearly: "Though random assignment is germane to the research goal of assessing whether the treatment may have caused any observed effects, it is conceptually irrelevant to all other research goals" (p. 343).

Common Objections to Random Assignment

Most of the common objections to random assignment in studies of program effectiveness do not dispute its utility as a tool for understanding causal connections. Instead, objections take other forms. Some are made in an attempt to avoid participation in a research study. Take the oft-made claim that 'random assignment is unethical' or that 'random assignment means denying services to some subjects.' These are political statements, either made without understanding what random assignment means or made in an attempt to retain control over which subjects are to be served by a given social program.

When there is an excess demand for a social intervention, program operators are in the position of denying services to needy families every day as they make decisions about which families are the neediest or the most deserving. As long as a randomized experimental study of such an in-demand program does not reduce the total number of subjects served, then there is no denial of services – the same aggregate number of families is served with or without an experiment. What an experiment does change is the mechanism for selecting which families receive the services; random assignment is used to decide who participates in the program instead of the judgment

of program staff. Thus, when program operators say that random assignment is unethical or involves denying services, they usually are saying that they do not want to give up the power to determine which families are served.

But what about denying services to families? Is this always unethical? Suppose a funding agency wants to learn about the effectiveness of one of its social programs and in the absence of evidence of effectiveness, the funding agency plans to withdraw its support. Suppose further that there is no waiting list and hence that a randomized experiment would make it impossible to maintain aggregate service levels since some families would be assigned to a control group. In this case, the ethical problem of doing an experiment which reduces the number of families serviced by a social program has to be weighed against the possibly greater ethical problem of not doing an experiment and risking reduced funding for the entire program.

An underlying, and typically unvoiced, objection to random assignment is that program staff or funders assume the effectiveness of social programs instead of worrying about whether scarce resources are being spent in the most appropriate manner. This is understandable, since scientific skepticism seems to counteract the ability of program operators to do their best work. But again, this is a political issue – that it is appropriate to assume the effectiveness of a social program instead of subjecting it to a rigorous test.

Another objection to random assignment is that assignment to a control group 'feels bad' to program staff and to the families they serve. The argument that randomization is like a lottery does not work in many social program settings. Why? Because a lottery usually has only one winner, and the losers can take solace in the fact that they are in the great majority. On the other hand, those assigned to the control group in a randomized study do not view their assignment the same way they view a lottery loss, since the odds of winning the lottery are miniscule, whereas the odds of being randomly assigned to the desired social program are usually 50/50.

Some other arguments are that randomized experiments are expensive (Levitan, 1992) or that they take a long time. The response to this sort of complaint is, "Compared to what?" A randomized experiment is expensive and time consuming when compared with the alternative of doing no research at all. But this is rarely a realistic alternative. Many quasiexperimental alternatives are just as expensive (any design in which data are collected from a treatment group and a nonequivalent comparison group) and time consuming (the common pre–post study) as randomized studies. Some alternative approaches are quick and inexpensive, for example, relying on data collected for other purposes. However, the fact is that none of these alternatives are capable of doing the one thing that randomized studies excel at – providing strong evidence about causal connections. The problem with using alternatives to random assignment to study program effectiveness is that even if they are less expensive, even if they require less time, even if they are easier to implement, they rarely are worth the time and money spent on them. Why? Because the results are not helpful for their intended purpose – for understanding program effectiveness. To paraphrase the common aphorism about education, "If you think randomized studies are expensive, try ignorance."

Conditions Making Random Assignment Easier

There are several circumstances that reduce the difficulty of implementing random assignment studies. Suppose an intervention program is in short supply and there is a list of subjects waiting to participate. This often happens with Head Start (the largest federal preschool program in the United States) projects in large metropolitan areas. If being placed on a waiting list means that a family is likely to miss a substantial portion of the Head Start year, then randomly assigning families from the waiting list to be in the program or in a control group might well be preferable to being on the waiting list with certainty. The absence of a waiting list does not mean that subjects are uninterested in a program. It often means that program staff do not want to spent time and energy on recruiting until they have openings. Hence, it is possible in short-supply situations for researchers to generate a waiting list by helping to recruit subjects and informing them about the planned study.

Suppose a treatment can be delayed with no ill effect on the participants. This is likely the situation in a school that wishes to test the short-term effectiveness of a one-semester school health curriculum. In this case, it would be possible to randomly assign students to take the school health course in the fall semester or in the spring semester.

Suppose a program's proponents are skeptical and are searching for the best solution to a social problem instead of trying to promote a specific intervention. Or, suppose a demand for evidence of program effectiveness cannot be ignored, for example, a congressional mandate. In these cases, political objections to random assignment are eased because program implementers are supportive of or at least are willing to cooperate with the research.

Suppose that a social program has many local projects, for example, the Head Start program has about 1600 local projects and the Even Start program (a family literacy program) has about 800 projects. An experimental evaluation of these programs could be done be selecting a relatively large number of projects and randomly assigning only a few subjects within each project. This approach minimizes the unpleasant effects of random assignment for any given project, making it more palatable to local program staff.

Assigning higher-level units is another way to ease the pain of random assignment. Suppose that there is an interest in testing three different solutions to a given social problem. One way to construct this test is to randomly assign individuals to one of three interventions implementing the three different solutions. A different approach which avoids many of the common objections to random assignment is to randomize groups of individuals. For example, a federal agency could hold a grant competition to test three different approaches to preschool education. School districts would not be allowed to receive a grant unless they indicated their willingness to implement any of the three approaches. School districts that receive grants would then be randomly assigned to implement one of the three preschool approaches.

Working Toward Correct Random Assignment

Random assignment is more likely to be successfully implemented if done by researchers and research organizations with

prior experience in conducting experimental studies. Certain research organizations have built the capacity to and reputation for conducting random assignment studies. Greenberg et al. (1999) report that almost half of the social experiments started in the US since 1983 have been done by three large research organizations.

In the same vein, random assignment is more likely to be successful if it is under the control of researchers rather than program implementers (Conner, 1977). The latter are likely to make exceptions or may misunderstand random assignment rules, even if those rules are carefully prepared by researchers. The research team does not have to be physically present in order to control the random assignment. One approach is to have program staff be responsible for recruiting subjects, explaining the experimental alternatives, and transmitting lists of study subjects to the research team via fax, email, or other means. The research team then does the random assignment and sends back listings of research subjects, sorted into treatment and control groups. A related approach is for the research team to prepare a random assignment computer program for use by program staff who recruit subjects and enter basic data on a microcomputer which does the random assignment on the spot.

The way in which random assignment is implemented depends on the way in which applicants are recruited for an intervention. Sometimes a large pool of applicants are recruited. In these cases, information on the entire pool can be sent to the research team at the same time, simplifying the random assignment. The process is more complicated when applicants enter a program on a rolling basis. In these cases, a random assignment algorithm has to be developed so that applicants are told their treatment/control status soon after they apply. However, simple assignment rules such as assigning the first applicant to the treatment, the second to control, the third to treatment, etc. are easily manipulated by program staff who often have control over the flow of applicants. More complex assignment systems are less subject to local control. For example, random assignment of families to an intervention could be done in blocks of four, where the order of treatment and control assignment is random within each block.

Preserving Randomization

Implementing random assignment is difficult. Once achieved, how can it be preserved throughout the life of an evaluation? One issue has to do with when randomization takes place. This involves tradeoffs between generalizability and internal validity. Families interested in participating in the Even Start family literacy program could be randomized as soon as they are first recruited for the program, after they have had the evaluation explained to them and have indicated their willingness to accept any of the alternatives, or after they have completed a 1-month 'tryout period' during which they can try Even Start and see whether they truly are interested in the program. Early randomization draws on the largest possible pool of families (increased generalizability) but risks losing many families (decreased internal validity) who find out that they are not assigned to the desired group or who leave the program after a tryout period. Late randomization winnows the pool of families (decreased generalizability) to those who are most likely to participate in the study (increased internal validity). Gueron and Pauly (1991) and Rieken et al. (1974) give additional examples.

Whether assigned to an intervention or a control group, subjects may refuse to cooperate with research measurements once an experiment has been started. Such attrition has the potential to destroy the comparability of the intervention and control groups. Clearly, it is best to use all means possible to avoid attrition of subjects. In some circumstances (e.g., studies of welfare programs), subjects can be sanctioned if they do not participate in research; in other cases, incentives for participation can be offered. Attrition is all but unavoidable in most social experiments since families move, are ill or otherwise unavailable for measurement activities, or simply refuse to participate in the research. Methods for determining whether attrition is related to the treatment and ways of dealing with this problem are discussed by Cook and Campbell (1979).

Are there ways to reduce the likelihood that subjects will refuse to go along with the randomization, or refuse to participate in the study? One approach is to plan the study so that subjects who agree to participate in the randomization have a better chance of getting the desired intervention than they would have if the study had not existed. This works best when there is a waiting list and when the intervention has a large number of openings relative to the number of subjects needed for the study. A second approach is to offer a competing intervention to members of the control group. This could work in several different ways. One competing intervention could be a financial or in-kind incentive for participating in the study. Another competing intervention could be a reduced or modified version of the treatment being studied. Yet a third alternative could be to offer control group subjects the opportunity to enroll in the desired intervention at a later point in time.

Rape and Sexual Coercion

Peggy Reeves Sanday, University of Pennsylvania, Philadelphia, PA, USA

Abstract

This article summarizes the biological and cultural approaches to the understanding of rape in human societies and evaluates these approaches by reference to studies demonstrating the incidence and social correlates of sexual coercion in the United States and cross-culturally. The biological, evolutionary view is compared and contrasted with the cultural approach proposed by anthropologists. The wide variation in the response to rape cross-culturally and intraculturally in the United States suggests that whatever the biological basis of male sexual aggression might be, family background and cultural context make a difference.

The Biological View

The biological explanation for rape and sexual coercion is grounded in the argument that sexual aggression is an evolved adaptation in human males. The argument builds on Charles Darwin's theory of natural and sexual selection. Natural selection is the doctrine that in the struggle for existence evolutionary progress is achieved by the inheritance of advantageous characteristics that prosper at the expense of less advantageous ones. Sexual selection is a specific case of natural selection applied to the evolution of sex differences. Darwin claimed that the greater size and strength of human males was due "in chief part to inheritance from his half-human male ancestors." According to Darwin, such characteristics "would have been preserved or even augmented during the long ages of man's savagery, by the success of the strongest and boldest men, both in the general struggle for life, and in their contest for wives." He measured success by the number of children some men left as compared with their "less favored brethren" (Darwin, 1936: pp. 872–873).

In the nineteenth and early twentieth centuries, the Darwinian doctrine of sexual selection was applied to treatises on human sexual behavior produced by the famous sexologists R.F. von Krafft-Ebing and Havelock Ellis. In his magnum opus, *Psychopathia Sexualis*, first published in German in 1886, Krafft-Ebing argued that "gratification of the sexual instinct [is] the primary motive in man as well as in beast" (quoted by Sanday, 1996: p. 125). In the third volume of his *Studies in the Psychology of Sex*, published in Philadelphia between 1897 and 1910, Ellis comes very close to making rape the *sine qua non* of sexual arousal. Ellis conceives of human sexual behavior as a game of combat. Playing the role of hunted animal the female conceals her sexual passion by adopting a demeanor of modesty in order that the male may be more ardent and forceful. Ellis claims that as the hunt becomes more sexually charged, "an element of real violence, of undisguised cruelty" is introduced. Accepting the Darwinian theory of natural selection with its emphasis on competition and brute strength, Ellis claimed that a woman who resisted "the assaults of the male" aided natural selection "by putting to the test man's most important quality, force" (quoted by Sanday, 1996: pp. 127–128).

At the end of the twentieth century, the Darwinian approach was again applied to the subject of the 'biological bases of sexual coercion' by Randy Thornhill and Craig T. Palmer in their book *A Natural History of Rape* (2000). Like Krafft-Ebing and Ellis, they make a distinction between sexual desire in human males and females. Citing the work of anthropologist Donald Symons (1979: pp. 264–267), these authors claim that rape is due to certain adaptations making males more easily aroused, with a greater sex drive, a reduced ability to abstain from sexual activity, in need of greater sexual variety, and less discriminating in choice of sexual partner (Thornhill and Palmer, 2000: p. 62). However, while Symons suggests that rape is a by-product of such adaptations, Thornhill and Palmer suggest that rape is itself an adaptation, which they call "the human rape-adaptation" (Thornhill and Palmer, 2000: p. 62). By this they mean that rape has a direct biological basis rather than being a behavioral consequence of other evolved behaviors.

To support their argument, Thornhill and Palmer (2000: p. 62) say it is necessary to identify "mechanisms involved in rape that were designed by selection in the past specifically for reproduction by means of rape." Because such mechanisms exist in the morphology of certain insects, they seem to suggest, they must also exist in humans. To make their case, the authors draw parallels with scorpion flies, which they point out have a physical adaptation for rape. Male scorpion flies have an organ, "a pair of clamp-like structures, one on either side of the penis," that serves to keep unwilling females in a mating position (2000: p. 63). Admitting that there is no "conspicuous morphology that might be a rape adaptation" in human males, Thornhill and Palmer (2000: pp. 64–65) look "to the male psyche for candidates for rape adaptations." They propose (2000: pp. 65–66) a number of 'psychological mechanisms' as 'adaptations' that can be viewed as 'analogous' to the rape adaptations observed in 'male insects.'

In a review of the argument put forward by Thornhill and Palmer, Frans B.M. de Waal, a prominent primatologist, points out that they have not demonstrated that rape in humans is a product of natural selection. According to de Waal, "for natural selection to favor rape, rapists would have to differ genetically from nonrapists and need to sow their seed more successfully, so to speak, causing more pregnancies than nonrapists, or at least more than they would without raping"

(de Waal, 2000: p. 24). "Not a shred of evidence for these two requirements is present" de Waal concludes (2000: p. 24). de Waal also points out that the psychological mechanisms Thornhill and Palmer propose do not demonstrate natural selection but have to do "with judgment of people and situations, a multi-purpose capacity also present in women" (2000: p. 24). de Waal's emphasis on judgment illuminates the fact of variation in the incidence of rape, which turns attention to the role of culture.

Early in the twenty-first century, Cheryl Brown Travis, Professor of Psychology and Chair of Women's Studies at the University of Tennessee, published responses to the Thornhill and Palmer argument authored by prominent anthropologists, evolutionary biologists, ecologists, philosophers, primatologists, psychologists, sociologists, and women's studies scholars. This was the first and most up-to-date volume providing multidisciplinary responses to essentialist biological claims regarding male rape from both a cultural and biological point of view. In her introductory article, Travis (2003: p. 4) points out that if evolutionary theory is to be used to understand gender differences and sexual aggression in particular, "it is necessary to take a considered look at basic principles of evolution and it is necessary to examine assumptions about gender in general." "Evolutionary theory is not sexist," she says. However, it can become so when applications of evolutionary principles to gender relations are characterized by grandiose overgeneralization and a politically charged gender philosophy. Travis (2003: p. 4) argues instead "that there should be a broad understanding of gender and of sexuality as phenomena that are as much social as biological." This is a point with which the other authors in the book agree. Claiming that Thornhill and Palmer's book represents bad science, bad history, and bad politics, one of the authors, Michael Kimmel (2003: p. 222), concludes that the book "tells us less about 'the biological bases of sexual coercion' than the ideological fantasies of those who justify sexual coercion."

The Cultural Approach

Against a strictly biological explanation of human behavior anthropologist Clifford Geertz (1973: p. 46) argues that without cultural patterns (i.e., 'organized systems of significant symbols') human behavior would be shapeless and without direction, "a mere chaos of pointless acts and exploding emotions." Applied to sexual behavior, the cultural approach, accepted by many anthropologists and sociologists, suggests that sexual behavior is part of a broader cultural system that includes notions of masculinity and femininity, ideas about appropriate sexual relations, cues for sexual arousal, and messages about the consequences of sexual expression. As anthropologist Malinowski said long ago, "[s]ex in its widest meaning … is rather a sociological and cultural force than a mere bodily relation of two individuals" (Malinowski, 1929: p. xxiii).

Peggy Reeves Sanday (1981) puts Malinowski's claim to the test in a study of the sociocultural context of rape cross-culturally. Using a standard sample of band and tribal societies, she reports that 47% of the societies for which there was adequate information showed a low frequency of rape, compared with 18% that were unambiguously 'rape prone.' Commenting on the pattern of correlations revealed by her study, Sanday (1981: p. 5) concludes that rape by males is part of "a cultural configuration," which includes interpersonal violence among men as well as between men and women and male social dominance. Rape-prone societies are more likely to be characterized by male segregation in separate houses, an ideology of male toughness, emphasis on competition, low respect for women as citizens, and the absence of women in the public domain of economic and political affairs. In the more rape-free societies, there is an ethos of cooperation and consensus in human affairs. The social separation of the sexes is less marked and both sexes are more likely to hold exalted positions in public decision making and to be integrated and equal in the affairs of everyday life. These findings support Malinowski's observation, based on his fieldwork among the Trobriand Islanders of Papua New Guinea, that the expression of sexual behavior is consistent with social forms and cultural meanings.

Anthropologist Carole Vance (1984: pp. 7–9) also cites the diversity in human sexual practices to suggest that biology does not "directly or simply determine the configuration or meaning of sexuality." If this were the case, she argues, one would encounter uniformity cross-culturally rather than the startling diversity that actually exists in which "activities condemned in one society are encouraged in another, and ideas about what is attractive or erotic, or sexually satisfying or even sexually possible vary a great deal." Vance concludes that "the body and its actions [must be] understood according to prevailing codes of meaning." She suggests that an important question for research must be "What is the nature of the relationship between the arbitrariness of social constructions and the immediacy of … bodily sensations and functions?" For similar points, see articles in Caplan (1987).

In two books, Sanday expands the understanding of the cultural foundation of acquaintance rape in the United States by examining fraternity gang rape on college campuses (1990) and the legal and historical contexts of rape in the United States (1996). Sanday (1996: p. 26) coins the term sexual culture to describe the system of meanings, standards, and expected behaviors by which male and female sexuality is judged and understood. She argues that in the United States, theories like those of Darwin, Krafft-Ebing, and Ellis functioned as cultural templates for popular sexual stereotypes by means of which males and females judged appropriate sexual behavior and acted accordingly. Because these stereotypes condoned sexual aggression by making it 'natural,' such as seen in the idea that 'boys will be boys,' US rape laws applied primarily to the use of force by a stranger. This changed after feminist activism in the 1970s resulted in more stringent legal codes. The same activism initiated studies of the incidence and social correlates of rape on US college campuses showing that acquaintance rape was much more common than stranger rape (Sanday, 1996: pp. 161–207). In her ethnographic study of "fraternity gang rape," Sanday (1990) demonstrates how alcohol is used to "hit on" young women guests in the "hooking-up" sexual culture prominent on college campuses that snares unsuspecting young women.

Rape Statistics in the United States

US statistics come from numerous studies utilizing national, community, or college samples. In general, these studies define rape as nonconsensual sexual intercourse irrespective of whether the parties know one another. Nonconsent is defined using the modern legal definition of rape. In most states, rape is defined as nonconsensual sex either due to the use of force or taking advantage of a person's inability to consent because of intimidation or because of alcohol or drugs. Although most studies of the past focused on heterosexual rape, most now include same-sex rape as well.

The first study designed to measure the percentage of those claiming they had been raped in a specified sample population was conducted in 1957 by sociologist Eugene Kanin on a college campus. This survey revealed that 55% of the 291 college women interviewed said they had experienced offensive episodes "at some level of erotic intimacy." Twenty-one percent said they were offended "by forceful attempts at intercourse" and 6.2% by "aggressively forceful attempts at sex intercourse in the course of which menacing threats or coercive infliction of physical pain were employed." Of the latter group, 48% told no one and none reported to anyone in authority (Kirkpatrick and Kanin, 1957: pp. 53, 56).

Another well-known path-breaking study was conducted by Diane Russell in 1978 in San Francisco. Russell interviewed 930 women ranging in the age from 18 to 80 years of diverse social classes and racial/ethnic groups. Twenty-four percent of the women interviewed reported at least one completed rape, and 31% reported at least one attempted rape. The majority experienced rape by acquaintances and a much smaller percentage by strangers (Russell, 1984: pp. 34–38).

Two large-scale national studies yielded similar results. In 1985, Mary Koss joined with *Ms*. magazine to survey a national sample of 6159 students on 32 college campuses. This study found that many more women and men were having sex in the 1980s compared to the figures reported by Alfred Kinsey in his landmark studies of male and female sexual behavior published in the 1940s and 1950s. One-quarter of the men interviewed in the Koss–*Ms*. study reported involvement in some form of sexual aggression, ranging from unwanted touching to rape. A high percentage of the males did not name their use of force as rape. Eighty-eight percent said it was definitely not rape. Forty-seven percent said they would do the same thing again (summarized by Sanday, 1996: pp. 191–192; see also Koss, 1988, 1992; Warshaw, 1988).

One in four of the women surveyed by Koss said yes to questions asking about behaviors that in most states would be legally defined as rape or attempted rape (for this definition see above). The power of popular stereotypes for defining acceptable sexual behavior and the adversarial nature of these stereotypes is reflected in the fact that most of the women reporting incidents that would legally qualify as rape did not call it rape. The term 'date rape' evolved from this study because many of the women surveyed said that the behavior often occurred on dates. Although most did not call it rape, Koss reported that "the great majority of rape victims conceptualized their experience in highly negative terms and felt victimized whether or not they realized that legal standards for rape had been met" (Koss, 1992: pp. 122–126).

By the end of the 1990s, a number of scientifically designed research studies revealed similar statistics (for a summary of studies, see Koss, 1993; Sanday, 1996: pp. 184–206). The findings reported in these studies are corroborated by a national study of sex in America conducted in 1992 employing a representative probability sample of 3432 Americans (see Michael et al., 1994). The findings fall within the range of many other studies: "22 percent of women were forced to do something sexually at some time," while "just 2 percent of men were forced." The authors of this study concluded that "as many as one in five women" experience some form of sexual coercion, including rape, in the United States (Michael et al., 1994: pp. 33, 221–222).

During the first decade of the twentieth century, despite the attention given to 'date' and 'acquaintance rape' in the l990s in the sexual assault policies adopted on many campuses, acquaintance rape statistics did not change. Verbal consent and a partner's ability to withdraw consent continue to be more debated than observed. Alcohol use continued to play a role in the sexual culture of acquaintance rape. Rape statistics reported by various colleges and universities resembled those reported in the late twentieth century. One study, funded by the Department of Justice published in 2007, found that approximately one in five (19%) women surveyed experienced attempted or completed sexual assault during their years in college. Close to the same number (15.9%) reported attempted or completed sexual assault before entering college. Many of the college women said that the incident occurred during their first or second year and was tied to alcohol. A large number also reported that they were at a party when the incident happened (Krebs et al., 2007).

Some campuses now administer occasional surveys to monitor the local incidence of acquaintance rape. The University of New Hampshire (UNH), which is especially known for its support, prevention, and monitoring policies, is one of the few institutions to both conduct campus surveys at regular intervals and publish the findings. In its 2006 survey, UNH compared data for this year with survey results for 2000 and 1988 showing a slight downward trend. Unwanted sexual contact was reported by 35% of women surveyed in 1988 as compared with 20% of those surveyed in 2000 and 23% in 2006. Unwanted sexual intercourse was reported by 10% of women surveyed in 1988, 6% in 2000, and 5% in 2006. The perpetrator's use of alcohol was mentioned in the large majority of cases both of unwanted sexual contact and sexual intercourse for each of the three reported years: www.unh.edu/news/docs/2006unwantedsexualexperiences.pdf.

The relationship between alcohol and rape is evident in a study by the Harvard School of Public Health conducted during the years spanning the late twentieth and early twenty-first centuries. This study surveyed female students at 119 schools representing a national cross section of students enrolled at 4-year colleges. During the 3 years of the study (1997, 1999, and 2001), a total of 23 980 female students were questioned. Roughly 1 in 20, or 5% of these students, reported being raped since the beginning of the school year. Seventy-two percent experienced rape while intoxicated. These young women tended to be under 21, white, resided in sorority houses, used illicit drugs, drank heavily in high school, and

attended colleges with high rates of episodic (binge) drinking (Mohler-Kuo et al., 2004: p. 37).

It is now more common to include males in local collegiate surveys. In the 2006 survey conducted by the UNH, mentioned above, 10% of men reported experiencing at least one unwanted sexual contact; 4% unwanted sexual intercourse, and 8% (as compared with 11% of the women respondents) reported that they had sexual intercourse when they were too intoxicated to consent. The 2009 stats for a southeastern college, published internally about the same time but not for distribution, found that 8% of males reported sexual touching against their will, 3% attempted rape, and 2% reported being raped. This tendency to now include males reflects the growing recognition that sexual equity applies to both sexes with respect to issues regarding consent.

The Social Correlates of Rape in US Studies

A number of studies conducted late in the twentieth century indicate that the adversarial view of male–female sexual interaction described by the early sexologists is frequently held by sexually coercive males. In a study of a large southeastern university, Boeringer (1996: pp. 137–139) reports that 56% of the males he interviewed admitted to obtaining sex by verbal harassment (i.e., "threatening to end a relationship unless the victim consents to sex, falsely professing love, or telling the victim lies to render her more sexually receptive"). One-quarter of the males reported using drugs or alcohol to obtain sex and 9% reported at least one use of force or threatened force to obtain sex. Boeringer concludes that such verbally coercive tactics suggest an "adversarial view of sexuality in which one should use deceit and guile to win favors from a woman" (p. 140).

Sexually aggressive men, from convicted rapists to college males answering questions on social surveys, share a remarkably similar set of attitudes. Most believe that sexual aggression is normal, that sexual relationships involve game playing, that men should dominate women, that women are responsible for rape, and that relations between the sexes are adversarial and manipulative on both sides (Koss and Leonard, 1984: pp. 221, 223). Reanalyzing Koss' data to pinpoint attitudes held by the self-admitted sexually aggressive men of her study (i.e., those who admitted to forcing a woman to have sex in Koss' 1985 questionnaire), Sanday (1996: pp. 196–197) found that these men often expressed adversarial-like beliefs. For example, many stated that they believe that a woman's No means Yes and that women say no to intercourse because they do not want to seem loose but really hope the man will force her. Compared with men who do not admit to forcing a woman, more of these men also think that being roughed up by a man is sexually stimulating to women and that women have an unconscious wish to be raped. Few of the women in Koss' sample hold such attitudes.

Prevention

Examples of prevention strategies based on the biological approach are offered by Thornhill and Palmer (2000: pp. 169–88). Believing that rape occurs "in all the environments in which humans societies [sic] have been known to exist" (p. 171), they are less interested in changing the environment by challenging popular stereotypes than with focusing on the "exact nature of the psychological mechanisms that guide male sexual behavior" (p. 172). They offer a number of suggestions including certain types of educational programs. Citing the view of rape proposed by Camille Paglia, Thornhill and Palmer (2000: p. 183) claim that since men "have evolved sexual preferences for young and healthy women and are attracted to women who signal potential availability by means of dress and behavior," women should be informed of the risk factors and use the information to lower their risk of rape by paying attention, for example, to dress and appearance. They also suggest more direct social interventions such as separating vulnerable females from males.

The cultural approach argues for a change in rape laws and sexual stereotypes so that nonconsensual sex is treated unambiguously as a crime. Increasingly, this approach defines rape not just in terms of the use of force or drugs, but more broadly as failure to obtain verbal consent. The operative words of the new American sexual ideology are 'affirmative verbal consent,' 'freely given agreement,' and 'sexual communication.' Increasingly, this sexual ideology is supported publically by male public figures.

A notable example can be found in an address given in 2011 by Vice President Biden addressing an audience of some 600 students at UNH kicking off its annual 'sexual awareness month' now observed on many campuses.

> Look guys—all you guys in the audience—no matter what a girl does, no matter how she's dressed, no matter how much she's had to drink—it's never, never, never, never, never okay to touch her without her consent. This doesn't make you a man—it makes you a coward. A flat-out coward. (US vice president Joe Biden, 4 April 2011)

The tone of this talk and the events surrounding it marked another turning point in the cultural history of acquaintance rape. The US government is now playing a stepped-up public role. More men are participating in the struggle for sexual equity. Other developments suggest optimism for the future. Policies on many campuses are now in place to support students, prevent rape, and engage in oversight by measuring the incidence of acquaintance rape. These policies are supported by changes in the legal arena leading to more prosecutions of rape (see Sanday, 1996; for updated developments see Afterword in the 2011 Random House ebook edition).

The public, legal, and political actions to stem the incidence of acquaintance rape can be likened to Darwin's view of natural selection because they promote sexual health and well-being in an era of sexually transmitted diseases. One point left out of discussions of the biological bases of rape is the fact that as much as Darwin stressed competition, he also stressed cooperation or acting on behalf of what he called "the general good or welfare of the community" (quoted by Sanday, 1996: p. 288). Called 'altruism' by students of human evolution, some suggest that the primary selective pressure in human

evolution was not for violent men but for those who were able to cooperate with women and other males in organized food gathering. Some anthropologists believe that this ability to cooperate was responsible for the evolution of human culture (Tanner, 1981). In light of the ever-increasing incidence of sexually transmitted diseases together with the evolution of nuclear weapons, one can also note that today there is a fine line between aggressive behavior that results in reproductive success as argued by the biological approach and behavior that leads human populations to the brink of extinction.

Conclusion

There is considerable evidence suggesting that whatever the biological basis of male sexual aggression might be, family background, and cultural context make a difference. The incidence of rape is far lower among men raised in stable, peaceful environments be it a family context in a complex society like the United States or the intimate communities of many small-scale traditional societies in which the ethos is one of mutual respect between the sexes. To say that some men will rape in all societies and to use this fact to make generalizations about the sexual predilections of all men may bring about the very sexual culture one is trying to avoid by creating a lore that makes sexual aggression a 'natural' part of masculinity. More important for the education of young males is the conclusion based on studies in the United States and cross-culturally that most men in most societies do not rape, and those who do face social rejection or incarceration.

Abstract

Rational choice theory (RCT) is based on the premise of individual self-interested utility maximization. Organizational theory (OT) is based on the premise of efficient functioning of organizations through means/ends rationality within organizations. Organizational economic theory, which consists of transaction cost economics (TCE) and agency theory (AT), forms an indirect link between RCT and OT. However, TCE and AT differ in their grounding premises. Thus, economic organizational frameworks, which purport to link micro-level RCT to meso-organizational theory, are unable to do so, due to the incompatibility of the premises on which RCT and OT rest. As one set of premises are assumed, the other becomes problematic. No OT has successfully integrated RCT and OT.

Rational choice theory (RCT) is based on the premise of individual self-interested utility maximization. Organizational theory (OT) is based on the premise of efficient functioning of organizations through means/ends rationality within organizations. Organizational economic theory, which consists of transactions cost economics (TCE) and agency theory (AT), forms an indirect link between RCT and OT. However, TCE and AT differ in their grounding premises. Transaction cost theory holds to the premise of OT that organizational rationality dictates that organizations are efficiently designed means/ends mechanisms, in some cases more efficient than markets, and finds that the RCT premise of individual self-interested utility maximization is problematic under conditions of uncertainty and asset specificity. AT holds to the premise of RCT that individuals are self-interested utility maximizers, but finds that the OT premise, that organizations function efficiently, is problematic. Thus, economic organizational frameworks, which purport to link micro-level RCT to meso-organizational theory, are unable to do so, due to the incompatibility of the premises on which RCT and OT rest. As one set of premises is assumed, the other becomes problematic. No OT has successfully integrated RCT and OT (Scott, 2014).

RCT and OT are two different, yet – in the works of some neoclassical economists, rational choice sociologists, and economic organizational theorists – closely related theories. RCT is used by economic organizational theorists as a method of aggregation. Specifically, it is used when it is necessary to link the change in actions of individuals with change in characteristics of organizations. However, organizational analysts generally take a broader view in which organizational context, organizational structure, and individual actions interact and move together to change organizational functioning. Such a perspective does not rest on the assumption that aggregated individual choices explain organizational behavior. In some cases, OT explains how individual actions articulate with structure. In other cases, OT does not deal with individual actions. Rather, it deals with articulating relationships between and among organizational and contextual characteristics.

The purpose of this analysis is to compare RCT with OT. RCT is based on the premise of self-interested, utility-maximizing actions/choices of individuals. OT is based on the premise of organizational rationality, the efficient functioning of organizations through means/ends relationships. Organizational economic theory, which consists of TCE and AT, forms an indirect link between the RCT and OT. First, differences by defining the origin and premises of RCT and premises of OT are elaborated. This is followed by demonstrating the link between the two, as developed in the premises of transaction cost analysis and AT. Although transaction theory holds to the premises of organizational efficiency, it finds the premise of self-interest utility maximization problematic. On the other hand, while AT holds the premise of self-interested, utility-maximizing individual choice of RCT, it finds the guiding premise of OT, the efficient functioning of firms, to be problematic. Thus, even the economic organizational theories, which purport to link RCT and OT, are able to do so only if they accept either the RCT premises or the OT premises. As one set of premises is assumed, the other becomes problematic and becomes the questions to be examined in the analysis. No OT has successfully integrated RCT and OT.

Rational Choice Theory: Origin and Premises

RCT originates in the British utilitarian tradition, via neoclassical economics. It is the core of classical economic theory. Although often qualified beyond recognition to meet conditional constraints of organizational analysts, it has been adopted in sociology (social choice) and in political science (public choice, game theory). In OT and analysis, rational choice is most often used for the development of economic models of organizations. TCE and AT are the dominant economic organizational perspectives.

The premises at the basis of RCT as derived from neoclassical economic theory are: (1) self-maximizing individual utility-driven actors, unconstrained by others and social norms (Coleman, 1990, p. 503); (2) actors possess complete

information and knowledge of their tastes, existing resources, the resources of others, and market characteristics of the products and services they seek; (3) actors calculate and recalculate the changing conditions and act rationally; (4) however, preferences do not change, they are stable, and they are givens often implied from the very behavior they are to predict; (5) actors are not emotional, irrational, impulsive, habitual in their choices, they are rational; and (6) interaction is defined as an exchange between buyer and seller achieved when utility and cost converge in a market transaction of supply and demand equilibrium.

RCT is an axiomatic system that provides a basis for making individual decisions/choices. The axioms of RCT define rational choice on the basis of choices between pairs of alternatives, which meet the axiomatic requirements of: consistency, transitivity, independence, continuity, and monotonicity. Consistency demands that it be possible for all the decision-maker's options to be ranked. The assumption of consistency is also called the assumption of connectedness. Preferences must be either equal or unequal. Unequal preferences can be rank ordered for comparison across the decision-maker's entire set of preferences. Transitivity is the assumption that if A is preferred to B, and B is preferred to C, then consistency requires that A is preferred to C (Green and Shapiro, 1994, pp. 14–15). The distance between preferences or magnitude of preferences does not have to be known to the subject or the analyst. Independence assumes that all preferences are independent of all other preferences. The continuity assumption is that preferences hold across time and space. Rational choice theorists assume monotonicity – all decision rules and preferences are stable across individuals and time. Allowing for assumptions of interpersonal variation produces enormous tractability problems (Storm, 1990, p. 126). Another assumption of RCT is that individuals "maximize the expected value of their payoff measured on some utility scale" and that, usually, "numerical probabilities can be attached to different eventualities" (Luce and Raiffa, 1957, p. 50). Eventuality is calculated as the value of the outcome "weighted by the probability of achieving it" (Elster, 1986; Harsanyi, 1986).

Organizational Theory: Origin and Premises

RCT and OT are brought together by the term rational. However, the term has different meanings (Zey-Ferrell, 1981) for RCT and OT. RCT is based on the idea that an individual seeks to maximize his/her utilities as he/she conducts organizational business. The central tenant of rational choice is that individuals at all levels of organizations act selfishly based on their own preferences to maximize their utility. This is rational individual behavior. OT defines rational as the way in which economic organizations are designed – the most efficient method of organizing. This is rational organizational behavior.

Rationality in OT originates in Weber's ([1922]1968) concept of 'rational bourgeois capitalism,' which connotes the systematic organization of ideas, people, and resources in the interests of instrumental efficiency and effectiveness. He wrote that rationality and its accompanying bureaucratic organizational form, based on formalization of the rule of law and differentiation of functions, pervaded not only the modern economy, but public administration, the legal system, and religions. The rationalization of bureaucratic structures led to increased efficiency. In Weber's model, organizational rationality and rationalization are essentially the same. This is not an (micro-level) individual process as it is in RCT. It is an organizational process or specification of mean/ends relationships based on systematic calculation and recalculation to achieve the most efficient organizational functioning. Subsequent analyses of organizations have assumed that this rationality is the basis of organizations and developed theories around this premise.

Divergences of Rational Choice and Organizational Theories

In addition to definitional divergence of the term rational, the most apparent divergence is the difference in the unit of analysis. RCT attempts to explain individual choice behavior. RCT is based on the utility-maximizing behavior of individual choice, while OT is based on the assumption of efficiency-seeking organizational design. OT explains behavior of organizations. The utility-maximizing behavior of individuals and the assumption of efficiency-seeking organizational design are similar, but are at different levels of analysis. If the unit is the individual, the utility being maximized is individual owner or employee self-interest. If the unit is the organization, the utility being maximized is profitability. Profitability of the firm does not always translate into income or other self-interests of firm members. Likewise, rational efficient organizational functioning does not always maximize the self-interest of organizational members.

Economic organizational theorists define organizations as firms doing business in markets. Neoclassical economists begin with market assumptions and work backward to firms and individuals assuming that actors operating in firms act in ways consistent with the theory of the market. However, assumptions that hold for RCT do not hold for organizational actors (March, 2014). Let us take one assumption, i.e., assuming that all actors have full information about costs. Because each of them knows the cost and adjusts the quantity of their purchase, it is reasonable to assume that the market will settle on an equilibrium. In organizations these assumptions are false. Many types of decisions are not afforded to each actor. The choices available to each actor are not the same. Some actors' choices impose constraints on the choices available to others. Some actors do not know that a particular choice exists, for example, information about pending mergers and acquisitions. During mergers and acquisitions, parts of corporations maintain secrecy, not only from other firms, but from other units of their own firm and individual within their own units (Zey, 1993, 1999). For example, securities firms are required by law to construct walls of secrecy, e.g., 'Chinese Walls' between M&A units and traders to prevent insider trading. Information is also kept secret to prevent oppositional reactions to present and new allocations of organizational resources. Information is not equally distributed among or within organizational units for deliberate power-based reasons. Finally, the norms of organizational rationality, efficiency dictates that various units within an organization

should not receive the same information, but only what is necessary for their organizational entity. For all units to receive all information would be inefficient.

The Link between RCT and OT

Although RCT and OT are based on different premises and units of analysis, one type of theory, organizational economic theory, has attempted to link the two sets of premises and units of analysis. There are two dominant perspectives in organizational economic theory: TCE and AT.

Economic organizational theory, both AT and TCE, begins with the relationships between individuals and organizations that are often conceptualized as events or transactions in which goods and services are exchanged (transaction cost analysis) and as contracts, which are agreements to conduct specific transactions (agency analysis). One is immediately aware that the unit of analysis is aggregated individuals. Transactions and contracts are aggregated either cross-sectionally or over time. In contrast, OT deals with the properties and characteristics of organizations, not individuals.

Coase (1937), from whom Williamson (2010) elaborates his TCE, explains the origin of firms as alternatives to inefficient markets, while organizational theorists observe that people create organizations to generate income and power, to create larger empires with which they are identified, for themselves or groups to which they belong. Mergers to create new organizations often take place to take advantage of new technologies, to take advantage of tax changes, or to reposition the organization in a growing market. These changes may have little to do with rational economic organization or inefficient market functioning.

Convergence and Divergence of Economic Theories of the Firm and Organizational Theory

TCE and AT, generally labeled economic organizational theories, have attempted to link RCT and OT and their different units of analysis and methods of theorizing through a set of assumptions that aggregate utility-maximizing individual behavior so that their behavior promotes organizational efficiency (profitability). However, survey research has demonstrated that not everyone has the same (or even individually consistent) utility. Thus, the aggregation, specifically nonadditive aggregation functions, of individual choices and action into organizational actions is not clear-cut, because the complexity of the aggregation process often violates RCT assumptions.

Furthermore, the two economic organizational theories, AT and TCE, do not operate under the same premises. AT is based on the utility-maximizing individual of RCT (Jensen, 1983, 1993; Jensen and Meckling, 1976), while TCE assumes that humans are boundedly rational at best. AT attempts to explain why organizations are more or less efficient while TCE assumes that organizations are an efficient alternative to inefficient markets (Williamson, 1975, 1985, 1996). The utility-maximizing behavior of organizations is efficiency-seeking organizational design. If the unit of analysis is the organization, and the utility being maximized is profit, then efficiency maximization is implied when income seeking is not compromised. Organizational theorists question these assumptions because organizations, even firms, are never constraint-free and individuals within organizations do not operate under the same constraints.

AT assumes that individuals are utility maximizers, but does not assume that organizations are structured in the way they are because it is the most efficient method of organizing. This is demonstrated, not only in the assumption that managers and workers act as opportunistic agents – that is, not in the interest of the owners – but also by the preoccupations of agency theorists with governance and methods of controlling nonowners to maximize profits (returns to shareholders) to the owners (Jensen and Ruback, 1983). Agency theorists and economic organizational theorists in general do not integrate into their analyses historical changes, which provide opportunities and constraints on individual and organizational actions as organizational theorists do. Jensen's presidential address to the American Finance Association demonstrates that he had not until recently discovered Chandler's work (1962, 1977, 1990) and that organizational forms, which are most efficient, change over time with each historical context in which they develop.

TCE assumes that organizations are structured in the way they are because it is the most efficient method of organizing, but TCE does not assume that individuals within organizations are utility maximizers. For example, in *Markets and Hierarchies* (1975), Williamson assumes that organizations more efficiently eliminate (by management fiat) opportunistic ('self-interested with guile') individual behavior than market mechanisms. TCE theorists analyze uncertainty and asset specificity of transactions. Individual utility maximization is problematic because of the obvious tendency of rational actors to act opportunistically under conditions of uncertain and asset specificity. TCE, like AT, ignores historical changes and processes which constrain and provide opportunities for organizations. Both contextual and organizational changes are ignored. Organizational change, especially transformational change, cannot be explained by economic theories of the firm (see Zey and Swenson, 1998, 1999). This is problematic because of the major transformations of firms at the turn into the twenty-first century.

In both Williamson's TCE (1975) and in Jensen's AT (Jensen and Meckling, 1976), the idea of self-interest in contractual arrangements between and within organizations is problematic. Ultimately, questions of reconciliation of differential self-interest in the absence of trust are impossible. Trust, rules of fairness, norms of reciprocity, and conflict are nonexistent and irrelevant in RCT and economic theories of the firm. They are essential to organizational formation and perpetuation.

Neither TCE nor AT holds both the basic premise of RCT, self-interested, utility-maximizing individuals, and the basic premise of OT, that firms are designed in the most efficient form of organizational design. AT holds the former, while TCE holds the latter. Each finds the other's basic premises problematic and grist for the mill of organizational analysis. Thus, economic OT has not yet integrated RCT and OT. This author does not think it is possible to do so because of conflicting premises and different units of analysis (**Table 1**).

Table 1 Rational choice theory (RCT) and organizational theory (OT): ideal-type contrasts

	Rational choice theory	*Organizational theory*
Intellectual Origins	Neumann and Morgensterns Milton Freideman Oliver Williamson Michael Jensen	Max Weber and Herbert Simon
Unit of analysis	Individual	Organization
Content of analysis	Preferences	Characteristics of organization and relationships to context
Human nature	Self-interested	Self- and other interested
Rationality	Individual, self-interested utility maximizer	Means/ends efficiency of functioning
Utility maximization	Self-interests	Profits in firms
Human preferences	Fixed hierarchy	Variable over time and place
Basis for interaction	Assumed trust	Trust is problematic
Constraints	Economic actions are constrained by tastes and scarcity of resources	Organization actions are not only constrained by scarcity, but also by social structure and historical context
Method	Predictive and explanation not descriptive. Formal, mathematical model building no empirical data (clean hands)	Many methodologies comparative, historical based on data from empirical observations (dirty hands)

Rational Choice Explanation: Philosophical Aspects

Russell Hardin, New York University, New York, NY, USA

Abstract

Rational choice explanation is the progeny of the Scottish Enlightenment and neoclassical economics. It is essentially reasoning from economic assumptions of what actors value to reach conclusions about both individual actions and aggregate- or collective-level outcomes. It is applied to virtually any significant behavior or social outcome, from political participation, crime, and drug addiction to institutional structures, legislative and interest group politics, law, norms, failures of collective action, and revolution. The most extensively developed parts of such theory are in democratic theory, the analysis of law under the rubric of law and economics, the study of group behavior, and game theory.

There was a time – the era of Hume and Smith – when it was natural to frame economic and political–philosophical social analyses as a singular coherent enterprise, not partitioned into unrelated disciplines. That breadth of understanding has been taken for granted in contemporary rational choice, in which the focus is on explanation, especially on individual motivations.

Rational choice explanation is the progeny of the Scottish Enlightenment and neoclassical economics. It is essentially reasoning from economic assumptions of what actors value to reach conclusions about both individual actions and aggregate- or collective-level outcomes. It is applied to virtually any significant behavior or social outcome, from political participation, crime, and drug addiction to institutional structures, legislative and interest group politics, law, norms, failures of collective action, and revolution. The most extensively developed parts of such theory are in democratic theory, the analysis of law under the rubric of law and economics, the study of group behavior, and game theory. Rational choice explanations gain their power from the attempt to reduce particular motivations to some narrower set of motivations, often simply to interests, which can be moderately well defined and measured across a large variety of contexts and actions. The article surveys game theory and rational choice value theory, and it applies rational choice explanation to collective action, democracy, voting, norms, and social order.

The most common criticism of rational choice explanation is that it is false to the facts of actual motivations and actions of people. This is a by-inspection claim. Because very much of actual behavior surely is motivated by interests, the dispute must actually be whether rational choice explanation is likely to help understand certain activities but not others. This is a question that cannot be answered in the abstract. Sometimes the criticism of rational choice trades on the fact that we commonly resolve many apparent choices by acting from habit or routine. As A.N. Whitehead quipped, civilization advances by the reduction of more and more choices to habit. A similar criticism of utilitarianism is that, if we spend as much time in calculating costs and benefits of our choices as would seem to be necessary to get our choices right, we will have no time left for life. J.S. Mill (1969) responded, rightly, that a sailor need not work out the positions of the stars anew each trip to sea but can simply rely on an astrolabe.

To illustrate the nature and power of rational choice explanation, as well as its plausible limits, I will address the aggregate-level phenomena of collective or group action, majority rule, and democracy. I will then address game theory and the value theory of rational choice. Finally, I will address the application of rational choice explanation to norms and social order.

Fallacies of Composition

A common criticism of rational choice explanation is that it cannot handle aggregate-level phenomena because it is fundamentally grounded in individual-level interests, choices, and actions. On the contrary, the chief successes of such theory have been to relate aggregate-level phenomena to individual-level actions. Several of the most important findings have been the – typically negative – demonstration that various aggregate-level claims are fallacies of composition from individual-level actions, choices, or values. It is a fallacy of composition to suppose that a collection of items has itself the characteristics of those items. This can be true, but it must be shown and not merely assumed. Consider three of these demonstrations.

The logic of collective action suggests that, although individuals may share a general interest in supplying themselves some collective benefit, they individually may have no interest in contributing effort or resources to the project. My contribution will buy a small part of our good, of which an even smaller part will go to me, so that my cost of contribution will be larger than my benefit from my contribution. All members of a group may therefore be individually worse off because they failed to take some action (Olson, 1965; Hardin, 1982). This is a problem that is pervasive in societies, ranging from very small societies with limited resources to very large and complex industrial societies.

The Arrow theorem (Arrow, 1963; Barry and Hardin, 1982) concludes that a collective utility or welfare function cannot be aggregated from individual utility functions if both are ordinal (see discussion of ordinal utility theory below). In essence, the theorem says that there cannot be a collective preference that has the simple features of an individual preference function. Among the implications of this theorem

 http://dx.doi.org/10.1016/B978-0-08-097086-8.63070-2

is that every standard choice procedure is potentially incoherent. Majority rule, for example, can produce cyclic preferences such that candidate A would defeat B by a majority, B would defeat C, and C would defeat A. Hence, simple majority rule is potentially indeterminate. It often works well enough – or seems to work – in practice, however, because there might not be cyclic preferences or because there are devices that block such preferences from being effective and even from being revealed. For example, plurality elections or the use of run-offs between the top two candidates in a multicandidate election can hide any cyclicities because there cannot be cycles over only two candidates.

The economic theory of democracy explains why candidates might not be substantially differentiated in certain common contexts and why voters often have little interest in voting. It also makes sense of the otherwise surprising level of ignorance of typical voters. In this latter case, however, there may be no fallacy of composition, because individual-level ignorance often translates into collective ignorance. Consider the problem of voting, as analyzed by Anthony Downs (1957). The chance that my vote would make a difference in an election decided by a large electorate is very nearly nil. In a 1974 statewide contest for senator in the very small state of New Hampshire, with somewhat more voters than Iceland, the vote was so close that errors in counting made it practicably undecidable who had won. No-one's single vote mattered. Suppose that the trouble to me of voting is such that I would sooner spend several dollars to vote by telephone to avoid going to the polls. The value to me of electing one candidate rather than another would have to be in the many thousands of dollars to offset my costs of voting, because the benefit would have to be discounted by the very low likelihood that my vote would make a difference. Yet many people do vote. Much behavior seems not to fit the rational choice theory and must be explained in other ways.

If it would not be worth my very slight effort to vote, Joseph Schumpeter (1950) concludes, then it would be even less worth the much more substantial effort it would take for me to be well informed about the candidates and issues at stake. Evidence from many national contexts suggests, in fact, that citizens are abysmally ignorant when they vote. Here rational choice explanations seem to fit well. Editorial campaigns against voter ignorance are often misframed as being about the irrationality of citizens, who are acting all too rationally.

Game Theory

Rational choice explanations are commonly based in game theory, neoclassical economics, or commonsense arguments such as those of Smith and Hume. Game theory is perhaps the framework that best characterizes the nature of most of the problems in rational choice theory, although many of the most important insights in such theory predate game theory, which originated roughly during World War II (Von Neumann and Morgenstern, 1953). Although it is called a theory, game theory is little more than a descriptive framework on which many theories about particular or quite general phenomena are founded. That framework takes many forms, the most transparent of which is the matrix form in which each of the players or participants faces a set of possible strategy choices. Outcomes of a play of a game are jointly determined by the strategy choices of all the players.

This characterization of our individual choices – of strategies, not of outcomes – makes game theory virtually antideontological. Judging action types as right or wrong makes no sense in interactive contexts, which are the principal contexts for most of moral theory. An action theory that takes what are essentially individual choices of outcomes as central is almost irrelevant to the choice in social contexts in which, typically, important outcomes necessarily are not under the control of individual deciders (Hardin, 1988: pp. 68–70). An ethic of rules makes nonsense of choices of strategies, which are chosen because of their effect on outcomes, as these are influenced by the strategy choices of others. Game theory can readily be fitted to consequentialism and especially utilitarianism. Utilitarianism essentially generalizes the principle of rational choice to choosing the welfare of all instead of only the welfare of the individual chooser.

To fit utilitarianism to game theory is to revamp its central concern with outcomes as valued by their benefits and costs. In interactive social choice, we typically cannot say that a particular action is right or wrong in producing a good overall outcome. We must, rather, judge strategy choices and we must judge them contingently. A strategy choice is right only to the extent that, in interaction with the choices of others, it produces a good overall outcome. If the others with whom I am interacting are sometimes utilitarian, sometimes self-seeking, and sometimes rule-guided in their choices, I may have difficulty determining my best strategy choice for producing a utilitarian outcome. This is not different from the difficulty that self-interested players have in determining the best strategy choices for themselves. Game theory is indeterminate in many contexts, and therefore both pragmatic and utilitarian choices in a real-world setting are apt to be indeterminate as well. Merely seeing the nature of interactive choice in descriptive game theory changes our understanding of the possibilities of rational choice theory and of utilitarianism.

Value Theory: Interests, Consumptions, and Welfare

Rational choice accounts are commonly grounded in interests. Sometimes, interests are the whole story of someone's motivations in a particular context. But typically, my interest in having more resources, such as money, is itself grounded in my desire to consume various things. Resources, capabilities, and opportunities matter to us only because they enable us to consume or experience various things, and consuming or experiencing these things is what constitutes our welfare. Resources are worthless otherwise. Focusing only on interests is therefore a shorthand for what the resources can enable us to do. Moreover, we could relate our consumptions to the overall welfare that they bring us. It would be a mistake to suppose interests translate smoothly into welfare or consumptions. Indeed, consumptions typically trade off against each other and against interests. If I invest much of my resources in a holiday, I may not have enough left for other things, such as a new refrigerator. Rational choice explanations involve all three of these categories – interests, consumptions, and welfare.

It would also be a mistake to suppose that my welfare is wholly self-interested. One of the things I might wish to consume or experience might be your happiness. One may say this is against my interests because it means using resources that I could use for my own happiness in some other, perhaps more direct, way. But this is a confusion in at least two ways.

First, the only point in having resources is to be able to consume in order to contribute to one's welfare, as is evident to everyone but a Scrooge for the resource of money. True, there is a conflict between using my resources for one consumption and saving them for another, but this is properly seen not as a conflict between consumptions and interests but as a conflict between different consumptions, or between different paths to welfare.

Second, there is no reason to suppose that, say, enjoying an opera, a good meal, or a lovely journey is a more direct or more successful route to enhancing my welfare with some bit of my resources than providing for my son's or lover's, or friend's happiness with that same bit of resources. More generally, my welfare is enhanced best by a mixture of consumptions and experiences, including contributions to the welfare of others, especially certain others. With those certain others, my welfare will depend on our sharing intentions to do various things for and with each other.

If we could suppose that economic interests as measured in resources were the primary issue for people, we could fairly easily explain actions as though people were all alike except for their circumstances. Rational choice explanations typically reduce the focus to interests, rather than other demands, such as demands for moral positions (ranging from deontological to utilitarian). In part they do so for methodological reasons. Analysis is more productive if we keep it clean and focused, and simplification is required for virtually all social analyses. But in part, the focus on interests is often basically right, especially for aggregate or collective issues. Other concerns matter to collective groups and societies, but they matter the way they do in life more generally. They often do not conflict with interests although, of course, occasionally they do and they may even trump interests in many contexts. For example, voters may vote against their personal interests in support of welfare programs and policies favoring ill-represented ethnic groups. But those who voted against the British Raj in India, French control of Algeria, or the US involvement in Vietnam may generally have voted with their interests as well as with moral concern. Still, many social and individual phenomena cannot readily be explained as the product of interest-seeking by individuals.

Value Theory: Cardinal, Ordinal, Ramsey–Neumann Cardinal

Apart from the structure or content of the value theory discussed above, there has been extensive debate over the form of such theory. Jeremy Bentham supposed that pleasures and pains during a day of someone's life could be defined in such a way that we could add the value of pleasures and subtract the value of pains for an overall measure of benefit to the person for that day. Today, we would speak of such a welfare or utility measure as cardinal in the sense that each experience one has could be assigned a utility number that could be added straightforwardly to other utilities.

Bentham's terminology was confused in that he spoke of the utility one gets from consuming some object and also of the utility inherent in the object. The latter notion underlies the labor theory of value that corrupted much of economic thinking throughout the nineteenth century and often still corrupts it today, in part under the doleful influence – on this matter – of Karl Marx. Bentham contributed to two opposing streams of value theory: One is that of the labor theory of value and the other is that of the subjective theory that holds value to be strictly what a person gets out of an experience or consumption. The value to me of consuming something such as, say, beluga caviar might be far below the value to me of consuming other things that take equal expenditures of my resources. The value to you, even with the same overall level of resources, might be radically higher. Hence, you might consume a lot of beluga caviar and I might consume none after an initial taste. The subjective theory obviously has the disadvantage that we cannot always generalize from one person to others, although often we can generalize enough not to need to do in-depth studies of the tastes and preferences of everyone in order to explain the overall behavior.

Bentham supposed further that the utility for one person could be added to that for another. This supposition would allow us to add up the utilities to all under one set of circumstances and to compare the total to that under another set of circumstances. Supposing we could do the measures, we could then say that, for example, one form of government is superior to another.

The so-called ordinal revolution in demand theory in economics overthrew all of the cardinal assumptions and set in their place a utility theory that is entirely subjective and that cannot be given interpersonal comparisons. The remarkable fact for economics is that such a limited theory clears up many prior problems and makes coherent sense of demand and supply relationships and, hence, prices in market exchange. Unfortunately, this revolution came only in the 1930s when moral theorists had ceased also to be economic theorists, as Smith, Hume, Mill, and Henry Sidgwick had been. It has therefore not had as much influence in general social theory as in economics, although it clearly should be brought to bear on the former as much as on the latter. A clear implication of interpersonally noncomparable value theory is that many traditional questions of interaction between people cannot be readily settled, so that moral and social theory must often be open on many issues.

In what might count as a minor sideline, Frank Ramsey (1931) and John Von Neumann (Von Neumann and Morgenstern, 1953) independently proposed a way to cardinalize preferences that are merely ordinal. Suppose you face a list of mutually exclusive outcomes, and suppose you can rank order any two outcomes. Assign a value of 0 to the least preferred, Z, and a value of 100 to the most preferred, A, outcomes in your list. For some outcome, K, between these two in your ranking, you can rank it against any lottery over A and Z. For example, suppose you would be indifferent to getting K and getting the combination of a p% chance of getting A and a $100 - p$% chance of getting Z ($0 < p < 100$). On the scale of 0–100, K has a cardinal value to you of p.

The Ramsey–Von Neumann (RN) cardinalization of utility clearly applies to personal decisions over outcomes. But we cannot use it to construct a Benthamite cardinal utility that is additive across persons, because there is no sense in which your 0 and my 0 are the same or your scale and mine, because each of them is arbitrary. If I assign a value of p and you assign a value of q to outcome K, we cannot meaningfully say that K has a joint value of $p + q$. Indeed, we can perform a linear transformation on your utility scale without affecting the results that follow from it. For example, we could divide the value of each outcome by 10 and add 37 to it, so that your scale would then run from 37 to 47, and this transformed scale would get all the results that your original scale from 0 to 100 would get. In addition, we can assign utility values to outcomes that fall outside the original ranking from A to Z, so that some outcomes might have negative utility and others might have extremely large positive values. This is suggested by the fact that the original normalization was performed over the arbitrary set of outcomes from A to Z. Hence, there is no meaning to any claim that your RN utility can be added to mine to yield an overall joint utility. The RN theory is therefore primarily of interest in individual decision making under risk, and is seldom of interest for more general social theory. It is irrelevant to Benthamite hopes for a cardinally additive utilitarianism.

Norms

There is a growing literature on the rational choice explication of norms. Edna Ullmann-Margalit (1977) gave rational reconstructions of norms for dealing with strategic contexts that are modeled by prisoner's dilemma, coordination, and partiality or unequal coordination games. In this categorization, the descriptive apparatus of game theory is used to establish and characterize types of norms according to the strategic problems they resolve. The first of these norms essentially handles collective action problems because, without the force of the norms, many individuals would free ride, and any effort to provide a collective good would fail. The second handles such coordinations as the driving convention. That convention surely requires no norm to keep drivers in compliance with it, because the threat of grievous harm from violating the convention is sufficient. But many conventions are less regulated by such clear incentives and some of these might be more forceful if backed by norms. Norms in Ullmann-Margalit's third category handle unequal coordinations such as the division of labor by gender roles or social order in any hierarchical society in which obedience to norms might keep even those at the bottom of the hierarchy loyal and orderly. Again, these conventions are grounded in coordination incentives and they might be fully self-enforcing, but norms that moralize the inequalities might make those in the less well off positions less sullen in acquiescing in the arrangements.

More generally, we may say that there are two broad categories of norms: norms of exclusion and universalistic norms (Hardin, 1995: chapters 4 and 5). Norms of exclusion are specific to particular groups, which can enforce the norms by sanctioning violators within the group; the sanctions can go so far as to shun and even exclude members. The sanctioning is grounded in the interests of individual sanctioners, so that the norms are commonly interest based, although group members might claim they are inherently moral or right. A norm of exclusion can work to help enforce cooperativeness in a group or community, or to enforce a coordination that might serve the interests of some but not all. For example, a minority culture might enforce upon its members the use of a minority language or a particular dress code. Using that language or following that dress code might reduce the possibilities for some members of the community to gain employment outside the community. The community might protect its hegemony over deviant members by shunning those who violate the language or dress code.

Universalistic norms can be dyadic, as in promising or truth telling, or large-number in the sense of applying to actions toward the whole society, as in not littering. Dyadic norms are commonly enforced through the sanctions inherent in the iterated prisoner's dilemma. If you lie to me or break your promise to me, I can simply avoid further interaction with you, to your likely cost. If you break a norm that affects everyone, such as a norm against littering or in favor of voting, no particular individual is likely to have an interest in sanctioning you. Hence, such norms are likely to be relatively weak in their force and in our adherence to them. Oddly, therefore, it is the often odious norms of exclusion, such as racist and ethnic norms, that have strongest force, while universalistic norms are relatively weak unless they are played out essentially in dyadic interactions. Those who insist that, morally, norms should commonly trump interests, should be bothered that it is interests that trump any plausible moral content of many norms, and that norms not backed by interests are likely to be weak. Large-number universalistic norms may be backed primarily by moral or psychologically inculcated commitments. If so, then it is of interest whether they are, in fact, very effective in motivating people.

Social Order

There are three grand schools of social theory. One, associated with the French sociologist Émile Durkheim and many others, holds that society is held together by shared values. The second, associated with Karl Marx, and Plato's *Thrasymachus*, holds that conflict is pervasive and that social order must therefore be maintained through the imposition of power to coerce when necessary. The third, associated with Adam Smith, holds that society is organized by and for exchange, which involves a combination of coordination and conflict. Each of these schools has many strong contemporary advocates. A fourth plausible view is that much of social life is simply organized by coordination (Hardin, 1999: chapter 1). We need not share particular values in order to share interests in avoiding conflicts with each other. The ideal type of this last form of social order is coordination on traffic rules, especially on the rule to drive right (or to drive left). We can be hostile to each other in many ways and still find it sensible to avoid needless conflict over many things, so that we would willingly be coordinated. A shared value theory is also a coordination theory, but its advocates ground it in value commitments and are generally hostile to the inclusion of interests among those value commitments. The conflict and exchange schools

are commonly grounded in interests, although the socially destructive conflict that sparked much of early liberal thought was over commitment to divergent religious views.

The preeminent coordination theorists among classical political philosophers were Thomas Hobbes and David Hume. They were both protogame theorists in their grasp of the fundamental nature of various social interactions. While Hobbes is commonly thought to be a major conflict theorist, his actual resolution of the problem of social order is to arrange for coordination on an all-powerful sovereign, whose task is essentially to coordinate us on order so that we may construct our own separate lives and engage with one another in productive pursuits (Hobbes, 1968). Hume's (1978: book 3) articulation of a remarkable array of coordination problems qualifies him to be seen as the greatest coordination theorist, although his complex insights were largely neglected for two centuries, in part because he lacked the technical vocabulary of game theory and did not himself bother to work out the general principles of it. He did, however, work out a general moral and political theory that was substantially grounded in strategic understanding (Hardin, 1988: chapter 2).

In complex modern societies, coordination may be the central, dominant mode of social order. It does not require consensus on values – pluralists can coordinate on an order for the society in which they seek their diverse values. It does perhaps fit especially well with modern individualist liberalism that allows individuals to live by their own lights. Indeed, coordination is a simple version of Mill's principle that we should be free to pursue our own ends without interference so long as our doing so does not interfere with others (Mill, 1977). When there is such interference, of course, other principles may be required to regulate our interactions.

Concluding Remarks

Rational choice theory is a diverse set of approaches to the study of society that are based in assumptions of individual rationality. Indeterminacies in such theory often mirror indeterminacies in social relations and individual understandings of these. Indeed, many rational choice explanations have demonstrated the indeterminacy of social choice (Hardin, 2003). Among the most important contributions of such theorizing is the descriptive clarity it often adds to our understanding of issues that have been poorly characterized before. Rational choice explanation is inherently about states of affairs, although it can include in a state of affairs concerns for anything that motivates people. It is therefore easy to see how it fits with utilitarianism.

Rational choice value theories, when introduced into the study of law, have led to the burgeoning movement of law and economics, which has produced the most systematic analysis of the broad sweep of law and legal rules that legal scholarship and practice have hitherto seen. The quick march of that movement – roughly beginning with the Coase theorem (Coase, 1988) – through virtually all areas of law has provoked counterattacks, but none of these is itself grounded in a value theory systematic enough to permit more than piecemeal objections. The Coase theorem says, with audacious generality and simplicity, that if there are no transaction costs to impede economic cooperation between owners of various resources, then ownership will not affect production, although it presumably will affect how the profits from the production are divided. That theorem, along with the earlier work of Ronald Coase and many others, has led to the massive study of transaction costs.

We have a rich understanding of the problems of rational choice value theories just because those theories have been a major focus in the development and articulation of the entire discipline of economics. The theories are a product of centuries of determined and often brilliant debate with dozens of major contributions. Alternative value theories have had far too few advocates and critics to yield much understanding at all. Indeed, value claims commonly seem to be ad hoc and not systematically generalizable. Such considerations are no argument for the superiority or rightness of any value theory. But they may be a tonic for those who wonder how the only well-articulated class of value theories is so easy to criticize: It has enough content to be subject to extensive and varied criticism.

Abstract

This article provides a short explanation of what rational choice theory is. Recent theoretical as well as empirical developments are discussed using the example of embeddedness effects. The theoretical developments address macro-level and micro-level extensions. The empirical part focuses on the value of using complementary research methods to test hypotheses derived from rational choice models. This article ends with some thoughts on future challenges and pitfalls for rational choice theory.

Introduction

Rational choice theory is a theoretical framework commonly used in various social sciences including economics, political sciences, and sociology. While in economics, rational choice theory has become the dominant paradigm, this has not been the case in sociology. On the contrary, rational choice theory has been widely criticized for its unrealistic assumptions, lack of empirical testing, and limited empirical validity (cf Green and Shapiro, 1994; Goldthorpe, 2000). While some of these criticisms are related to misconceptions of the interpretation of rational choice theory, others have been seriously taken up by researchers in the field. This has led to more research in which rational choice theory construction is combined with a variety of empirical tests. The *Handbook of Rational Choice Social Research* (Wittek et al., 2013) provides an extensive and recent overview of the literature in this area including theoretical advancements as well as a wide variety of empirical applications of rational choice social research. The handbook is not particularly restricted to sociology, but illustrates research and applications in economics, political science, and history as well (see Kroneberg and Kalter, 2012 for another recent review focusing on Europe and Hechter and Kanazawa, 1997, for an earlier overview focusing on family, gender, and religion). In this article, we first discuss the properties of the standard rational choice model, the so-called baseline model. Thereafter, we address extensions of the model in terms of macro-level conditions and extensions that elaborate on the micro-level assumptions related to individual behavior. We conclude with a short overview of properties of recent empirical research testing rational choice models and an outlook to possible future developments.

The Baseline Model

The classical baseline assumptions in rational choice theory comprise that actors are rational and selfish and that actors have one-shot interactions in a completely transparent context with complete information on all details of the setting. In economic terms, this implies that all interactions resemble atomized interactions in perfect markets. Clearly, rational choice theory currently comprises a much broader set of theories than those resembling neoclassical economic models. To structure current directions in rational choice theories, it is useful to distinguish extensions that focus on the macro level and the micro level. At the macro level, these extensions include broadening the assumption that all interactions resemble interactions in perfect markets and allowing more complex interaction structures in which also assumptions on information availability are relaxed. At the micro level, extensions include changes in the assumptions of rationality as well as relaxing the selfishness assumption. This distinction in extensions of rational choice models at the macro level and the micro level closely relates to Coleman's scheme in which macro-level phenomena are explained as a result of behavior of individual actors and in which macro-level conditions affect micro-level conditions for individual behavior. While micro-level behavior based on these micro-level conditions is aggregated back to macro-level outcomes (Coleman, 1990; see Raub et al., 2011 for an extensive explanation on Coleman's scheme and a sketch of its history). These macro-level outcomes are also the main interest for sociological researchers, because most sociological questions address how macro-level conditions lead to macro-level outcomes mediated through the decisions of individuals. Although there is a strong overlap between sociological models based on Coleman's scheme and rational choice models, not all micro–macro models are considered rational choice models.

Extensions at the Macro Level

The first type of extensions includes models in which the 'embeddedness' of actors is modeled in a more complex manner, for example, because actors do not interact only once but repeatedly and actors are organized in networks. For sociological questions, Coleman (1987, 1990) advocated to insist on simple and robust assumptions on rational behavior at the micro level, while indeed extending the assumptions on the social structure of interaction. This was also what Granovetter (1985) already advocated in his classic article on embeddedness in economic action. Of course, the realization that interdependences between actors have to be modeled in a more complex manner than assumed in the neoclassic model started much earlier and is already implied by the introduction of game-theoretic models in the late 1940s (Neuman and Morgenstern, 1944). In game-theoretic models, it is not assumed that the behavior of other actors is completely

determined by the external circumstances, but actors' outcomes resulting from actions of these so-called players in the game directly depend on the choices of other actors. Rational behavior in a game is defined as equilibrium behavior. The most well-known equilibrium concept is the Nash equilibrium (Nash, 1951). Strategies of actors fulfill the conditions for a Nash equilibrium in a game if none of the actors can improve his or her outcome by changing strategies and, thus, all actors play a best-reply given what all the other actors do. Thus actors are rational in equilibrium in the sense that they follow goal-directed behavior by optimizing their outcome given what others do. Note that strategies are complete specifications of behavior in a game under all possible contingencies that can happen in the game. For a more detailed account of game-theoretic terminology and textbook game-theoretic models, we refer to Rasmusen (2007).

We illustrate some key findings derived from more complex macro-level conditions based on a relatively large class of rational choice models, namely, the class of models that studies behavior in social dilemmas embedded in a social context. The key property of a social dilemma is that if in a single encounter actors follow their own self-interest and play equilibrium behavior, they obtain a worse outcome compared to when the players would choose the 'cooperative' option that would make everyone better off (e.g., Rapoport, 1974). A standard example of a social dilemma is the prisoner's dilemma (e.g., Axelrod, 1984) in which two prisoners get a 1 year sentence if they both confess, while they get a 3 year sentence if they both deny. However, if one denies and the other confesses, the one who denies gets no sentence while the other one gets a 5 year sentence. The implication is that whatever the other does, the focal actor can always best deny. If both actors do this, they are 3 years in jail, while if they would both confess they would only be 1 year in jail. Actors in a social dilemma can escape this trap if they do not have these interactions only once but repeatedly. For example, if the same actors play a dilemma sufficiently often (more precisely, if after every interaction the same actors play the same game again with a probability that is high enough), then there exist also Nash equilibria in which all actors always play the cooperative strategy (Friedman, 1971; Axelrod, 1984). Thus, the embeddedness of social dilemmas in series of repeated interactions changes the prediction from no cooperative behavior to at least a rational possibility also for cooperative behavior. If one would assume that a Pareto optimal equilibrium in which everyone is better off is more likely to result than a Pareto suboptimal equilibrium in which everyone is worse off, one would even indeed predict cooperation if the probability for repeating the game is large enough. Thus, these adaptations of the rational choice model are not only crucial because they take better into account macro-level conditions, but they also substantially change macro-level predictions.

Further extensions assume that not only two prisoners play repeatedly a prisoner's dilemma, but a network of prisoners play prisoner's dilemmas in pairs over time while the network takes care of information exchange about the behavior in the past. Raub and Weesie (1990) analyzed this model showing that more network embeddedness indeed increases the possibilities for cooperative behavior. In all these models, it is crucial that the prisoners do not know what the last time will be that they play. The reason is the so-called backward induction argument. In the last interaction, both actors know that they have no reason to be cooperative, and as a consequence they defect. But given that they will not cooperate in the last interaction, they also have no reason to be cooperative in the last but one interaction. This argument unravels until the very first round and, therefore, no cooperation is predicted for so-called finitely repeated games. The models become a bit more complex if we assume that prisoners are not completely informed about the sentences others will receive given the behavior of both prisoners (Kreps et al., 1982) and that there are some prisoners who have no incentive to deny whatever the other prisoner does. In these models, prisoners are also predicted to behave cooperatively if there are enough interactions to be played, and this result even remains valid if it is known what the last game will be. Although prisoners are the textbook example to illustrate the social dilemma, they are not the best example for embedded social dilemmas. Therefore, one should realize that the prisoners mentioned above represent, for example, buyers and sellers in purchase relations, students collaborating on assignments, partners running a household, and so on.

Examples on social dilemma research as provided earlier are still purely theoretical examples. Game theory is a strong tool, because it allows for many variations in modeling the context of social interactions and relaxing assumptions on who interacts with whom and what people do knowing about each other's preferences as well as who is informed about whose interactions. Still, these models are highly simplified at the individual level, which raises two questions: (1) Are the testable predictions derived from game-theoretic models corroborated by empirical research? (2) If predictions are not in line with empirical findings, is this due to elements at the macro level that are still simplified or are the assumptions on individual behavior wrong and in such a way that this affects the macro-level outcomes of behavior. Although the assumptions at the individual level are simple or, maybe better, parsimonious, they still imply complex rational deliberations of the actors and they also imply that the outcomes in the game reflect exactly the utility of the actors. This brings us immediately at the micro-level extensions. After these extensions, we pay more attention to some empirical work.

Extensions at the Micro Level

The second type of extensions focuses on relaxing the standard assumptions at the individual or micro level, namely that actors are rational and selfish. First, it should be realized that these are different assumptions. Rationality focuses on the ability of actors to optimize their well-being or utility given their preferences, while these can be, for example, altruistic or risk-averse preferences. Selfishness focuses on the extent to which actors optimize their own material benefits. Simon (1982) introduced already the idea of bounded rationality implying that actors are not necessarily able to optimize, but try to achieve an acceptable outcome in more adaptive ways. Limits of rationality occur because actors are not able to handle probabilities in a consistent manner in the sense of expected utility theory or

because actors have inconsistent time preferences. Alternative strategies actors can adhere to might be imitation (e.g., of successful others) or heuristics that lead to acceptable but not necessarily optimal outcomes. Extensive reviews of models on bounded rationality are provided by Gigerenzer and Selten (2001) and Gintis (2009). Lindenberg (2013) formulates a more psychological view on the issue interpreting human rationality as self-regulation in an adapted manner to a specific context or 'frame.' Many empirical examples exist for boundedly rational behavior such as the Ellsberg paradox showing that people often handle probabilities in an inconsistent manner or at least not in line with expected utility theory. Still, given that we know that boundedly rational behavior is not uncommon in certain situations, this does not imply that we need to assume bounded rationality to explain macro-level phenomena. This is necessary merely if the deviation from rational behavior not only affects micro-level decisions of some actors, but also macro-level outcomes for the group as a whole. This issue is discussed later.

The second type of extensions at the micro level relaxes the selfishness assumptions. Related theoretical arguments are developed in social psychology as well as in behavioral economics. In the literature on social value orientations (e.g., Van Lange, 2000), different types of actors are distinguished: individualists, cooperators, and competitors. Individualists only care about their own material outcome, while cooperators also assign a positive value to outcomes of others. Competitors assign a negative value to outcomes of others. While the social psychologists pioneered typifying these different types of social preferences and also accumulated considerable experimental evidence that not all people are selfish, they did not make the step to analyzing what this would imply for rational choice explanations on behavior in larger groups. Experimental economists realized that these different types of actors can be represented through different utility functions that specify how money for the focal actors and money for others can be translated to utility for the focal actor.

The most famous models in experimental economics are the inequality aversion model (Fehr and Schmidt, 1999) and the reciprocity model (Bolton and Ockenfels, 2000). The inequality aversion model by Fehr and Schmidt assumes that utility is based on what actors receive themselves and, in addition, that actors have disutility from differences between what they earn themselves and what others receive. This disutility does not need to be the same depending on whether the focal actor receives more or less than other actors in the game. Bolton and Ockenfels (2000) take a related approach assuming that utility depends on own monetary outcomes and the relative outcome of the focal actor compared to other actors. They focus on the threshold where the importance of the relative outcome takes over the importance of the own money, and thus where the argument more money is better does not hold anymore.

Both the Fehr-Schmidt as well as the Bolton-Ockenfels model focus on the outcomes actors receive in the game, but not on the path how actors reach the stages in the game. This is in contrast with more intention-based approaches by, for example, Rabin (1993) and Falk and Fischbacher (2006). In these models, behavior not only depends on the outcomes of the game, but also on the behavior experienced in the game. If one actor has to make the decision on how to divide a cake, this will typically depend on what happened before the division has to be made. The division will be, on average, fairer if the actor who has to divide the cake has been put in this advantageous position thanks to a decision of the other actor in the game than when the focal actor is put in this position, say, by an experiment leader. An additional assumption when making the rational choice model more complex in terms of rationality or selfishness is whether all actors are the same and, if not, what actors actually believe about the characteristics of other actors. Because given that it seems plausible that some actors are, for example, inequality averse, it is also likely that not all actors are inequality averse to the same extent and that actors realize that this is the case. So actors have beliefs about inequality aversion of others and they can update these beliefs based on past experience. As Aksoy and Weesie (2012) illustrate, these issues raise many new questions: do the beliefs of actors depend on their own characteristics? Is updating of beliefs done in a rational manner? To what extent do we need to take these beliefs into account to understand macro-level outcomes? Aksoy and Weesie's results suggest that, yes, beliefs depend on focal actors' characteristics and, yes, they seem crucial to understand macro-level outcomes.

There are various related approaches in which actors are goal-directed in their decisions, but not necessarily optimizing in the strict rational sense and also not necessarily selfish. Although these approaches are at least closely related to rational choice theory, even the authors in these approaches vary depending on whether they think their theories should be considered variants of rational choice theory or not. What they at least do have in common is that they are analytical in their derivation from explicit assumptions to theoretical predictions. One line of research is in analytical sociology as advocated by Hedström (2005; Hedström and Bearman, 2009). Hedström spells out his 'DBO theory' (desires, beliefs, opportunities) through which he elaborates his program on 'mechanism-based' explanations. Although many of the features in DBO theory resemble properties of more standard rational choice explanations, Hedström (2005: p. 41) seemingly does not consider this theoretical approach as a variant, but more as an alternative to rational choice theory and the discussion on this is still lively in the recent literature (Opp, 2013a,b; Manzo, 2013; Ylikoski, 2013). Note that experimental economists (e.g., Gächter, 2013) describe their approaches as based on preferences, beliefs, and constraints, which not by coincidence resembles the terminology in the DBO theory of Hedström.

Also different learning theories and agent-based simulation models (see Macy and Flache, 2009; Epstein, 2006) are variants of theories in which actors behave according to well-defined behavioral rules although these rules are mostly not rational, but more adaptive in nature and based on experiences actors had in the past. Still, they are worth mentioning here, because although the behavioral or micro-level assumptions are quite different, the macro-level consequences of these assumptions occasionally coincide with predictions from strict rational choice models. For example, the evolutionary stable strategies in evolutionary game theory (a variant of game theory in which indeed the actors react on past

experiences rather than that they base behavior on rational expectations about others) are a subset of the set of Nash equilibrium strategies under a broad range of assumptions (Weibull, 1995). While this is an example where indeed macro-level outcomes of other behavioral rules coincide with rational behavior, many of the adaptations of micro-level assumptions indeed lead to different macro-level predictions. For example, simple divisions of cakes (so-called dictator game outcomes) in the laboratory show that virtually all subjects give more than negligible parts of the cake to other actors in completely anonymous settings and without any future interactions. This behavior cannot be explained through selfish rational choice explanations, but can be explained by models of inequality aversion.

Links to Empirical Research

The value of all the extensions discussed earlier can only be judged by the empirical evidence that corroborates the new predictions of these extensions. Rational choice researchers have more and more learned to pay attention to the empirical testability and value of their theories after criticisms as posed by Green and Shapiro (1994). As a reaction on these criticisms that rational choice research was merely a collection of theoretical exercises, the amount of empirical research testing rational choice models has been seriously extended in the last decades. Related to the models on behavior in embedded social dilemmas, for example, Buskens and Raub (2013) provide an extensive overview of empirical research focusing on trust situations. Their overview illustrates the breadth of empirical research on rational choice models varying from laboratory experiments, via vignette experiments to also survey studies. The laboratory experiments on embeddedness effects in trust situations show that different mechanisms simultaneously affect trust. Actors learn from their own past experiences and others' past experiences whom to trust. Hypotheses on this are derived from learning arguments as mentioned earlier. Also without having previous experiences, actors are more trustful if they expect to have more future interactions with a partner. This corroborates the related hypothesis based on repeated game arguments that allow for cooperative behavior if enough future interactions are expected. The same hypotheses are then shown to be also supported in so-called vignette experiments. These are contextualized hypothetical decision situations for which students as well as experienced professionals answer questionnaires. Finally, the same hypotheses are tested and supported in a survey on buyer–seller transactions, which can also be considered trust situations. We claim that such a combined set of tests of the same hypotheses provides a really strong point in case for the related theory, because the theory is supported in settings in which the tests are very close to the specific causal mechanism as well as in actual daily decision making that is not hampered by the external validity problem. We have to indicate that actually one hypothesis is consistently not supported in our overview and that is the hypothesis that trust increases with possibilities for reputation building through a social network. This hypothesis also follows from an extension of the repeated game model on networks. The consistent lack of support of the hypothesis in various empirical contexts is a strong case that the theory needs to be made more complex for understanding these consistent deviations from the simpler model. One of our conjectures is that the issue is related to rationality, because the reputation effect via social networks is the most complex effect to be incorporated by the decision makers.

Certainly related to extension of the rational choice model at the micro level, the extent of empirical research investigating these extensions has been flourishing especially in the laboratory. As has been realized by many researchers, stretching the assumptions on the utility function by, for example, social preferences opens the possibility to explain post-hoc any behavior through a suitable utility argument (see Gächter, 2013 for a recent account of this). The same problem is true for relaxing assumptions on rationality. As a counter force, Gächter (2013; see also Fehr and Gintis, 2007, for an earlier account and Camerer, 2003, for an extensive overview) discusses the increasing possibilities of experimental research (as done in experimental economics, but also in many related disciplines). Laboratory experiments provide an empirical tool to critically and under controlled conditions study preferences of actors or other possible deviations from the micro-level assumptions of the standard rational choice model. Fehr and Schmidt (1999) advocate their inequality aversion model based on the claim that this relatively simple model explains behavior in many different games in the laboratory. Although this claim has been challenged for this particular case (Binmore and Shaked, 2010), the idea that extensions to the micro-level assumptions should be tested in a variety of contexts is exactly what is necessary to avoid theoretical particularism. Related overviews of experiments on variations of games (Fehr and Gintis, 2007; Gächter and Thöni, 2011; Gächter, 2013) show that some behavioral assumptions seem to reappear regularly in different contexts, while different settings also seem to have their own particularities for which not yet more general explanations are available.

Still, empirical research in the laboratory is only one way to test rational choice theory and in itself not a sufficient way. Because there are serious concerns on the external validity of laboratory experiments, which are often done only with university students, the real proof of the pudding is in putting the theories also at a test outside the laboratory (see Gächter and Thöni, 2011, for a more extensive review of advantages and limitations of experimental research including further references). The recent volumes on rational choice theory and related approaches (Hedström and Bearman, 2009; Wittek et al., 2013) illustrate that also in that respect rational choice research is well on the way.

Looking Ahead

Overlooking the developments of rational choice theory in the last decades especially also after the criticism of Green and Shapiro (1994), rational choice researchers have certainly taken up the glove and strengthened the connection between rational choice theory and empirical findings. In particular, the strong extension of experimental studies (Jackson and Cox, 2013) has enabled rational choice

theorists to test prediction under controlled conditions and provided the potential to measure directly preferences and beliefs. Another consequence of this is that the acceptance of 'thick' rational choice theories rather than 'thin' rational choice theories (Hechter and Kanazawa, 1997) has gained an importance, because the thin rational choice theories do not only seem to violate assumptions of behavior at the individual level, but also do not predict outcomes at the macro level accurately.

So although these developments in rational choice theory have advanced the state of the art quite a bit in the last decades, still several pitfalls need to be avoided. Although the laboratory work indeed is ideal to pinpoint behavioral regularities under different circumstances, the laboratory should not become the main empirical playground for sociology. While in earlier times, theorists were blamed for developing new models only for the sake of new models without an eye at where the model is about, experimentalists sometimes have the tendency to develop new experiments for the sake of the experiments. Such development would still keep the real-world applications out of sight. Experimental tests are meant to test specific theoretical predictions, which in the end should predict behavior also outside the laboratory. Thus, external validity issues of experimental tested are an important concern for social scientists. Therefore, not only the same theoretical extensions of the standard rational choice model should find support in many different experiments, but the same extensions should also be supported with data collected outside the laboratory. It would be of great value to future rational choice research if the same hypotheses would be tested with a multitude of empirical set-ups and researchers would be parsimonious with extensions especially at the micro level until empirical evidence accumulates that a specific hypothesis is not confirmed or that there is repeated evidence that specific behavioral assumptions are violated.

A final issue that might come up given the tendencies to make rational choice theories thicker is that by adding complexities, the consistency of the total theoretical set-up should be kept in mind. As the close reader might have noticed in our account of the studies on trust, some hypotheses were derived from learning models and other hypotheses from more classic game-theoretic models. For combining learning elements in standard game-theoretic models, incomplete information models need to be considered, which again pose very strong assumptions on the rationality of actors, for example, in terms of rationally of updating beliefs. Although the example illustrated that deriving all hypotheses within the same theoretical framework is not always self-evident, freely shopping from different potential extensions to 'thicken' rational choice models should be discouraged as well.

Abstract

Contemporary theories of rational behavior in human society augment the orthodox model of rationality both by adding various forms of bounded rationality and by relaxing the assumptions of self-interest and materialistic preferences. This article discusses how these extensions of the theory of rational behavior are increasingly applied to model rational behavior in society. First, the baseline model of rational behavior and its extensions are discussed, with particular emphasis on heuristics, learning theory, and theories of social preferences. Subsequently, applications to rational behavior in societal realms are addressed. Three areas of application are discussed in particular: production of collective goods, social networks, and rationality in organizations.

The orthodox model of rationality construes social actors as decision makers who always select the action that optimally serves their goals, given their information and the perceived costs and benefits of the available courses of action. Contemporary theories of rational behavior in human society augment this model in several ways (Wittek et al., 2013; *see* Rational Choice Theory in Sociology). Such modifications are necessary for several reasons. One reason is that empirical evidence shows that people have limited information processing and computational capabilities and find making multidimensional comparisons difficult. This has led to a range of models of 'bounded rationality' (Simon, 1997). Moreover, the orthodox model is silent on the contents of the goals rational people should strive for. Applications of the orthodox model of rational man, rooting in neo-classical economics (e.g., Cournot, 1838) typically fill this gap with two key assumptions on human goals in social behavior: actors are assumed to be selfish and exclusively interested in tangible material outcomes. But many social scientists criticize these assumptions because models of rationality based on them fail to explain many forms of real social behavior observed. In response to this, a range of theories of rational social behavior have been developed that attribute partially altruistic and nonmaterial preferences to human social actors, while retaining the core assumption that individuals strive to optimally attain these goals, albeit with bounded rationality. This article discusses how these extensions of the theory of rational behavior are increasingly applied to model rational behavior in society. We start from a discussion of the baseline model of rational behavior and its extensions. Subsequently, applications to rational behavior in societal realms are addressed. We focus on three areas of application: production of collective goods, social networks, and organizations.

The Theory of Rationality and Its Extensions

Rationality as Utility Maximization

Utility maximization and its extension of expected utility maximization (von Neumann and Morgenstern, 1944) are the best developed formal notions of rationality and form the core of neoclassical economics. Utility maximization as such does not explicitly refer to the social context of action. It postulates a utility function, which measures the degree to which an individual's (aggregate) goals are achieved as a result of their actions. The rational actor chooses the action, from among those given, which maximizes utility given his (rationally formed) expectations. If the actor's goals are food and sleep, then rationality calls for choosing the attainable combination of food and sleep that yields the greatest utility. But the core theory does not specify the content of the utility function (Lindenberg and Frey, 1993; Simon, 1983).

Without a concrete specification of what it is that generates utility, the theory has few refutable consequences since almost any choice can be rationalized by assuming a convenient goal. Thus, to increase the theory's empirical content additional assumptions must be made. Economic applications usually add the vastly oversimplified assumption that utility is measured by total income or wealth.

Without auxiliary assumptions, the theory is also silent about the processes used by the actors to find the optimal action. Neoclassical economics typically employs the assumption of perfect rationality in this respect. Rational actors never fail to find the action that maximizes their utility, even if this requires unlimited capacities to process and memorize all information available and to have unlimited foresight of the consequences of all available courses of actions in a distant future. More recent extensions of the theory of rationality relax both assumptions about actors' goals and assumptions concerning the process of decision making. We discuss both types of extensions below.

Bounded Rationality: Heuristics and Learning

An action may be regarded as rational because of the way it was chosen (procedural rationality) or because of its outcomes (substantive rationality) (*see also* Decision and Choice: Economic Psychology; Heuristics for Decision and Choice). Attributions of rationality may or may not respect the limits of actors' abilities to adapt actions to goals. Utility-maximizing behavior selects an action that is among those objectively available and attains a real-world optimum. As an alternative, bounded rational behavior selects some action from among those that memory, observation, and thought bring to attention. It is aimed at attaining outcomes that satisfice (attain aspirations) for the wants and needs that have

been evoked (Conlisk, 1996). There is a close affinity between optimizing and substantive rationality and an affinity between bounded and procedural rationality. The utility-maximizing optimum is independent of the choice process; the outcome is all that counts. In bounded rationality, the choice depends upon the process leading up to it. The social sciences, other than neoclassical economics, usually explicitly incorporate human cognitive limitations and social influences into their theories, using some version (seldom highly formalized) of bounded rationality. Bounded and procedural rationality require generating courses of action, assessing their possible outcomes under different futures and estimating how much satisfaction they will attain. They postulate procedures that respect human limits on knowledge of the present and future, on abilities to calculate the implications of knowledge, and on abilities to evoke relevant goals (Simon, 1983). Two important classes of models of bounded rationality focus on heuristics people use to make choices and on backward-looking learning processes.

Heuristics

Heuristics are the actual mental rules humans employ when making decisions such as choosing an action from a set of alternatives or deciding when to stop searching for a better option. A simple illustration is 'one-reason decision making' according to which individuals make choices based on the first relevant criterion that discriminates between the alternatives (Gigerenzer and Todd, 1999). Heuristics generally deviate from optimizing behavior in the sense that individuals are not assumed to gather all relevant information about all available alternatives before making a decision, even when such an exhaustive search was possible. Heuristics are adaptive decision-making rules (Gigerenzer and Selten, 2001) because they are in accord not only with human cognitive abilities but also with the information structure of the environment (Simon, 1956). Since they deviate from optimizing behavior, heuristics are necessarily linked to satisficing behavior (March and Simon, 1958). Originally conceptualized as 'deviations from perfect rationality' in the biases and heuristics program of Kahneman et al. (1982), work on heuristic decision making has shown that simple heuristics can actually outperform more advanced decision models. Recent developments in the decision literature focus on a 'dual mode model of decision making' distinguishing two mental systems, one fast, requiring little effort, and driven by heuristics, and one slow, effortful, and driven by conscious deliberation (Kahneman, 2011). Examining the interactions between these two systems and the conditions that determine which of the two systems is activated is a main frontier of this field of research.

Learning

The most simple approach to learning is reinforcement. Thorndike (1898) first proposed the 'Law of Effect.' If an action is associated with a favorable outcome, this makes it more likely that the decision maker repeats that action. Otherwise, alternative choices will be explored more likely. Reinforcement theory relaxes three key behavioral assumptions in models of forward-looking rationality (Macy et al., 2013). First, association replaces causality as the link between choices and payoffs. Decision makers explore the likely consequences of alternative choices and develop a propensity for those associated with better outcomes. But the outcomes that guide the exploration are those that have already been experienced, not those that a perfectly rational actor might anticipate to occur based on logical deduction. Second, reward and punishment replace utility as the motivation for choice. Decisions are guided toward better outcomes by two distinct cognitive mechanisms, approach (driven by reward), and avoidance (driven by punishment). This distinction means that aspiration levels are very important for learning theory. The effect of an outcome depends decisively on whether it is evaluated as gain or loss, satisfactory or unsatisfactory, or pleasant or aversive. Third, similar to heuristic decision making, reinforcement learning implies satisficing (March and Simon, 1958), not maximizing. Choices with satisfactory outcomes are likely to be repeated even if other choices have higher utility. In contrast, unsatisfactory outcomes induce searching for alternative outcomes, including a tendency to revisit alternative choices whose outcomes are even worse, a pattern called 'dissatisficing.' (Macy et al., 2013).

Reinforcement learning can lead actors out of 'social traps' where perfect rationality would entail socially undesirable outcomes. An important example is cooperation in a finitely repeated Prisoner's dilemma game (Macy and Flache, 2002). For perfectly rational actors, mutual defection in such a game is unavoidable. Whether the other player cooperates or not, own defection always leads to an outcome with a higher utility than cooperation does. However, if both players were to resist the temptation to defect, both would be better off. Reinforcement learners can escape from this trap if their aspirations are such that they are satisfied with an outcome in which the other player cooperates and are dissatisfied otherwise. In that case, actors will feel punished as long as the other player defects, resulting in avoidance of whatever action they have chosen themselves. As a consequence, actors keep changing their behavior until an outcome of mutual cooperation occurs. Then, the behavior of mutual cooperation becomes self-reinforcing because for both players it is associated with a satisfactory outcome. Unilateral defection would still yield a higher utility in this situation, but due to satisficing actors will not explore this possibility.

The theory of reinforcement learning is the most elementary theory of bounded rationality based on learning. In recent years, more sophisticated formal models of learning behavior have been developed that all share the principle that decision optimization is based on experience rather than anticipation. Theories differ in the extent to which rational forward-looking decision making is combined with learning. Bayesian belief learning and fictitious play, for example, are models of how decision makers form beliefs about the expected behavior of other actors in their social environment, to then determine the best reply given these beliefs (see Camerer, 2003; Macy et al., 2013; for brief overviews).

Goals

Social science and behavioral economics research has shown that the assumptions of selfish and of purely materialistic goals are empirically untenable. Research on social preferences has

cast doubt on the selfishness assumption, demonstrating that human decision makers do take the outcomes for other individuals into account for nonstrategic reasons. Forsythe et al. (1994) compare behavior in ultimatum and dictator games showing that pure altruism plays a considerable part in human (strategic) decisions. Several theories have been developed to account for findings like these, including and combining pure altruism (Andreoni and Miller, 2002) with motives such as spite (Levine, 1998) and aversion against unequal distributions, even when in favor of oneself (Fehr and Schmidt, 1999; Bolton and Ockenfels, 2000).

Regarding the standard assumption of materialistic preferences research has shown that human decisions are shaped not only by the distribution of outcomes but also by the perceived fairness of the social process through which the outcomes come about (Rabin, 1993). Charness and Rabin (2002) and Falk and Fischbacher (2006) proposed important models formalizing the idea that in social interactions human actors evaluate an outcome based on the perceived (un)kindness of actions taken by the other individuals involved. Moreover, the perceived (un)kindness of these actions is determined not just by their consequences but by the intentions attributed to the others. Intended (un)kindness then triggers a desire to reciprocate.

A main conclusion from this literature is that humans are heterogeneous in terms of social preferences, leading to classifications of actors in terms of having for instance selfish, inequality averse, surplus-maximizing, or competitive preferences. These distinctions between preference types chime with the social value orientation concept from social psychology (cf. Bogaert et al., 2008; *see also* Social Psychology, Sociological) that classifies humans as proselfs and prosocials. An important classification when it comes to intentions and reciprocity is the one between 'strong reciprocators' and selfish individuals (Fehr and Gintis, 2007), where the former are willing to punish and reward unkind and kind behavior, respectively, at a net cost to themselves. Importantly, when humans interact in groups the composition of the group in terms of social preferences and the interaction between these preferences and the institutional environment have a strong impact on behavior and outcomes.

Rationality in Social Context

In the following, it will be discussed how extensions of the orthodox model have informed the analysis of rationality in different social contexts, notably in the production of collective goods in society, in actor's embeddedness in social networks, and in rational behavior in organizations. More in general, the application of the model of rationality to the analysis of societal realms follows the approach of methodological individualism (*see also* Methodological Individualism in Sociology), where the aim is to explain societal outcomes from assumptions about individual behavior in social contexts.

Collective Goods and Rational Behavior

Collective goods benefit all individuals involved, but cooperation is required to bring them about. The problem is that cooperation is costly for those who contribute and cannot easily be enforced. Many authors therefore see the provision of collective goods as an expression of solidarity (Hechter, 1987; *see also* Solidarity, Sociology of). The reason why cooperation in the provision of collective goods is problematic is that collective goods are characterized to varying degree by 'jointness of supply' (i.e., consumption of the good by a given individual does not reduce the amount available to other individuals) and 'nonexcludability' (i.e., individuals who benefit from the good cannot be excluded from the consumption of the good, even if they did not contribute). 'Free rider' problems at the workplace and environmental pollution are two examples where cooperation fails due to the conflict between individual and collective interests. Nevertheless, for many collective goods a degree of cooperation is observed that is hard to explain by self-interest alone.

Orthodox models predict that (large) groups of individuals will fail to produce collective goods at a sufficient level in the absence of selective incentives (Olson, 1965). This is because the direct gains an individual obtains from her own contribution fall short from compensating the costs. Selective incentives (such as cheap insurance for union members) can alleviate this free-rider problem if they only benefit those who contribute (e.g., pay their union membership fees). However, the work of Marwell and Oliver (1993) on collective action theoretically establishes that the relations between rationality, group size, and the production of collective goods is much more complex than suggested by orthodox treatments. Their approach was developed with particular emphasis on explaining the dynamics of social movements (*see also* Movements, Social). They adopt a bounded rationality perspective in the sense that actors will invest if the immediate marginal gains for them exceed their marginal costs. With this, Marwell and Oliver exclude more sophisticated strategic calculations in which actors may withhold contributions in order to let others shoulder the burden, even if they themselves also would gain from investment. Based on this assumption, Marwell and Oliver show that rational actors can make considerable levels of contributions to the collective good if costs and benefits of contributions depend nonlinearly on the amount of investments already made (modeled in the 'production function' of the collective good) and there is heterogeneity amongst potential contributors in terms of their interest in and ability to contribute to the collective good. For example, models imply that a few particularly interested or resourceful individuals would be willing to shoulder high start-up costs in producing a collective good. They then form a 'critical mass' (Marwell and Oliver, 1993) that triggers subsequent contributions of less resourceful or less interested members, because under an 'accelerating' production function contributing becomes sufficiently cost-effective for the less interested or less resourceful once the collective action has successfully started up. A prototypical example for this are the dynamics of demonstrations against oppressive regimes (Opp and Gern, 1993) in which the risks from the participation decrease and the potential for success increases as more people join in.

In addition to considerations concerning the production function of collective goods much experimental evidence falsifies the orthodox prediction even for situations in which production functions are such that contributions are never cost-effective in material terms (Ledyard, 1995). Famously, Fehr and Gächter (2002) showed that allowing group members to

punish each other greatly improves the chances for successful collective good production even when the experimental set up assured that imposing punishment does not pay off for the enforcer. The authors explain this finding with the strong social preferences of enforcers.

The seminal work of Elinor Ostrom (1990) focuses on how the right social and institutional circumstances can overcome free rider problems in local communities. She offers a set of design principles that are conducive to good governance of 'common pool resources' (CPRs), such as drink water basins, forests, and community irrigation systems. For instance, clear lines of demarcation between users and nonusers are necessary; rules for the governance of the CPR should be attuned to local physical and social conditions, local needs, and local knowledge, and these rules should be drafted by community members themselves; regional and national governments should respect these local rules and accord the local communities sufficient autonomy; community members should monitor and sanction each other and an accessible and low-cost institution for conflict resolution should be created. While not explicated in her work, Fehr and Gächter's theory of strong reciprocity suggests an answer to the question why community members could be motivated to engage in such monitoring and sanctioning in the first place. Ostrom then focuses on the institutional features that further sustain monitoring and sanctioning. She also emphasized the importance of norms (*see also* Norms) and trust (*see also* Trust, Sociology of) between community members as social resources of a community. Importantly, in later work Ostrom et al. (1999) emphasize that the creation of local institutions is also a viable strategy for creating global collective goods, such as slowing down the pace of global warming. In these global cases, local institutions create systems of polycentric governance, which offer points of application for higher-level governance.

Rationality in Social Networks

Networks and Cooperation

A key theme in studies of rational behavior in networks is the relationship between social networks (*see also* Social Networks) and the solution of cooperation problems. Networks are of especial significance in two realms of cooperation. In bilateral interactions, such as between buyers and sellers, or in interfirm alliances, experiments with trust games and surveys have shown how the embeddedness of interacting partners in on-going network relations (between each other and with third parties) stabilizes the trust that is needed for cooperation (Buskens and Raub, 2002). Rational choice theories explain this through rational reciprocity based on conditional cooperation (Axelrod, 1984). Network relations serve as conduits for the flow of reputational information about other peoples' behavior (Buskens and Raub, 2002). Seen from this perspective, networks that allow for a fast and reliable spread of information (e.g., centralized networks) provide incentives for actors to cooperate, because their cooperation avoids possible future sanctions or disruption of a mutually beneficial reciprocal exchange. In the case of production of collective goods, research also has demonstrated how networks foster cooperation, for example in political movements (Opp and Gern, 1993) or organizational settings. Explanations from a rationality perspective in this research again invoke reputational effects on conditional cooperation and also refer to network relations as instruments to impose rewards or sanctions in terms of, e.g., social approval. But from a bounded rationality perspective using learning models, networks can also impede cooperation. In a collective good setting, free riders can learn to use their friends' dependence on social approval from the free rider to deter social sanctions (Flache and Macy, 1996). In terms of the learning approach used in this research, boundedly rational learners find it easier to coordinate on mutual social approval in a bilateral relationship than to coordinate on the more complex multilateral exchange of contributions to the collective good for social rewards. Satisficing then implies that mutual approval without provision of the collective good may be an outcome that is good enough for the actors, while mutual approval combined with collective good provision would still be superior. The possibility that trustful social relations hinder social control empirically resonates in the negative effects of high trust on monitoring that have been found in research on teamwork (Langfred, 2004).

Strategic Formation of Social Networks

Studies of the role of networks in collective action typically treat networks as static and exogenously given. An important new frontier in research on rationality in social networks addresses the role of rationality in the formation of social networks. A prominent line of research conceptualizes network evolution as a process driven by the strategic interaction of rational individuals (Dutta and Jackson, 2003). Models in this field typically assume that individuals' payoffs depend on structural properties of their network, also beyond their direct network neighborhood. A prototypical example is the formation of coauthorship networks. For example, decisions of one author to establish a coauthorship relationship with a colleague can affect the outcomes both of her current coauthors (because she may invest less time into other projects) as well as of the colleagues' coauthors (because the colleague may likewise invest less effort). Severance of an existing network link is typically a unilateral decision, but formation of a new link is either a unilateral or a bilateral decision, depending on the type of model. Individuals are assumed to make link formation and severance decisions independently and are assumed to be motivated by the desire to maximize the utility they obtain from the networks they create. In the models in this literature, the degree of rationality assumed is frequently very low. Typically, individuals are assumed to be entirely myopic in the sense of not anticipating on the reactions of other network members on their networking choices. In a seminal paper Jackson and Wolinsky (1996) show that under these assumptions there is generally a tension between efficiency and stability. Thus, in these models network formation exhibits central characteristics of a social dilemma: many networks that are stable (in the sense that no individual or pair of individuals can unilaterally or bilaterally profitably change their network connections) are not efficient (in the sense of yielding the highest overall payoffs). For example, in a coauthorship setting it may be individually rational to maximize the number of coauthorship

relations because every additional project increases scientific visibility, all other things being equal. At the same time, when everyone follows this strategy this may result in a reduction of overall productivity due to excessive costs of coordination of multiple projects.

Rationality in Organizations

In a modern society, formal work organizations – companies, government agencies, schools – provide environments for a large fraction of human waking hours (Simon, 1997). From a rationality perspective, organizations face difficult problems of coordination and cooperation between employees as well as between employers and employees (*see also* Organizations, Sociology of). At the same time, organizational structures can be seen as institutions (*see also* Institutions; New Institutionalism in the Analysis of Complex Organizations) that form an important part of the solution of these problems. Two prominent theoretical approaches that aim to explain features of organizations from a rationality perspective are principal-agent theory (Petersen, 1993) and transaction-cost theory (Williamson, 1981). Principal-agent theory views members of an organization as perfectly rational actors, typically with materialistic and strictly self-interested preferences. From this perspective, employees would only invest effort for organizational goals if the organization assures that 'shirking' provides inferior outcomes for the employee. Principal-agent theory analyses which features of payment and career systems provide this assurance given its model of man. For example, Petersen (1992) argued that this can explain why under group-payment systems higher levels of effort are obtained under target-rate payment schemes as opposed to piece-rate payment schemes in manufacturing industries. Broadly, the argument is that under a target-rate payment scheme every worker's contribution to the collective effort may be crucial for whether the target is met and thus the group bonus is obtained. In a piece-rate scheme, instead, the gains for an individual worker from investing effort are too small to compensate for costs, because the relatively small pay-increment achieved is spread across the entire group. Similar to Marwell and Oliver's (1993) nonlinear production function, target-rate payment thus reduces incentives to free ride in group production. Principal-agent theory also explains features of the career systems of many organizations. Often, organizations require employees to make large investments in terms of effort, training, and education in early stages of their career for comparatively low wages. Only at later stages of the career higher wages can be obtained. Principal agent approaches argue that organizations choose such structures to avoid 'adverse selection' in a situation of asymmetric information where the employer cannot know the true qualities and motivations of the employee. Only employees who are sufficiently motivated and have enough trust in their own abilities will stay with the organization in the early career phase in such a system, and other employees will self-select into jobs that bear lower risk but also lower payment in later career stages. The career system thus solves the cooperation problem employers and employees face. It assures that the 'right' employees are hired by the firm into a long-term career path which – in turn – provides for the firm the incentive to hire these employees in the first place even when information about their characteristics is inaccurate or incomplete.

Transaction cost theory differs from principal-agent approaches in assuming strongly bounded rationality. The theory then analyzes which features of a 'governance structure,' such as employment contracts or contracts between firms, are best suited to efficiently solve the cooperation problems between economically interdependent boundedly rational actors. The inability of boundedly rational actors to oversee all contingencies of an economic transaction makes contracting incomplete and provides room for 'opportunistic' behavior. According to transaction cost theory, this is the most important reason why hierarchical organizations exist. By integrating the different parts of a production process into a hierarchy, opportunism problems are more efficiently solved through means of hierarchical control. This is especially important when transaction-specific investments in human capital or technology create 'asset specificity.' That is, they create dependencies between contract partners that may give room for opportunistic behavior. For example, when employees need to make high investments to obtain skills that can only be used within a specific firm, this may deter an employee from obtaining the necessary training in the first place. The reason can be fear by the employee that the employer may later abuse the employee's dependence on the firm by making employment conditions less favorable for the employee. In such a case, a long-term labor contract with, e.g., guaranteed wages and career prospects can resolve the cooperation problem to the mutual benefit of both parties. While principal-agent theory and the transaction cost approach typically focus on monetary and contractual incentives in organizations, more recent elaborations add the importance of organizational features that appeal to social and altruistic motivations, such as socialization of employees into company cultures, professional identities, or professional norms (*see also* Norms). One early example of a formal elaboration of such 'soft' instruments of governance in a rational choice framework is the work of Kandel and Lazear (1992).

Conclusion

The goals rational actors pursue as well as the process of rational decision making itself are both shaped by their social environment and help to explain outcomes of social action. Recent developments in the theory of (partially) altruistic motivations, as well as heuristic decision making and learning, help to understand how cooperation in collective goods is possible and how social networks arise, change, and affect cooperative behavior. Moreover, theories of rational behavior in organizations help to understand the structure of organizations and the conditions under which employers and employees can successfully cooperate. Models of rational behavior suitable for understanding rationality in society turn out to be more complex and have more degrees of freedom than the orthodox model of man of neoclassical economics. Current work in rational choice social research (Wittek et al., 2013) focuses on identifying which mix of assumptions makes the rationality perspective most fruitful for addressing a particular societal context, as well as on moving toward an

integration of different perspectives into a general model of rationality in society.

Abstract

Rawls is often acknowledged as one of the most important political philosophers of the twentieth Century. Rawls' seminal work, *A Theory of Justice*, recreates social contract theory as a hypothetical thought experiment, thereby forming the basis for Rawls' liberal conception of justice as 'Justice as Fairness.' In his second book, *Political Liberalism*, Rawls transfers 'Justice as Fairness' into the political realm and considers the stability of 'Justice as Fairness' in a world of diverging religious, moral, and philosophical beliefs. Rawls' third and final book, *The Law of Peoples*, considers the application of 'Justice as Fairness' to global justice. This bio-entry aims to provide a short introduction to Rawls' life and his work, and to introduce readers to Rawls' most significant concepts including, without limitation, 'the original position,' 'veil of ignorance,' 'principles of justice,' 'overlapping consensus' and 'reasonable pluralism.'

Early Life and Education

Family Origins and Early Education

Rawls was born in 1921 in Baltimore, the second of five sons. His father, despite dropping out of law school, worked hard and became a successful and respected lawyer. His mother, heavily involved in the League of Women voters, fought for women's rights. Both his parents were very interested in politics and justice, and this permutated Rawls' early years.

Unfortunately Rawls' otherwise uneventful early life was twice struck by tragedy: In 1928, Rawls' younger brother Bobby caught diphtheria from Rawls, and sadly passed away. The incident shocked Rawls, and, according to Pogge, Rawls' mother thought it may have triggered the stammer that Rawls had for the rest of his life. Unfortunately a year later, tragedy repeated itself. Rawls' younger brother Tommy contracted pneumonia from Rawls and passed away while Rawls was recovering.

After completing his schooling in Baltimore and Connecticut, Rawls joined his older brother at Princeton. Rawls studied philosophy with Norman Malcom (previously Wittgenstein's student). He wrote his senior thesis on the topic of human evil and seriously considered studying for the priesthood. However, after graduation, like most of his classmates, he joined the army.

Wartime Experiences

Rawls was sent as an infantry man to the Pacific, where he served in Japan, New Guinea, and the Philippines. For Rawls his army service was 'singularly undistinguished;' however he was awarded a Bronze Star for work behind enemy lines. It is widely reported that in Japan, Rawls witnessed the devastated city of Hiroshima and almost 50 years after the war, Rawls would refer to the destruction of Hiroshima as a great evil (Rawls 'Fifty Years After Hiroshima' (1995) in *Collected Papers*). It is clear that Rawls' experiences in the army had a profound effect on him and Thomas Nagel wrote that Rawls' outlook was strongly marked by his experiences of "the deadly fanaticism of the Japanese army, the murderous romanticism of the Nazis and the calculated massacre of civilians by the Allies in Tokyo, Hiroshima, Nagasaki and Dresden."

Rawls' experiences in the army also lead to his disillusionment with religion. In 'On my Religion' (1997) in *A Brief Inquiry into the Meaning of Sin and Faith* Rawls details three incidents that influenced this disillusionment: The first occurred following a particularly brutal period of combat. A Lutheran pastor gave a brief sermon to Rawl's unit, during which Rawls recalled him saying "God aimed our bullets at the Japanese while God protected us from theirs." Rawls did not believe this was an appropriate use of Christian doctrine. The second was the death of Rawls's friend, Deacon, which perhaps was particularly profound for Rawls as he so easily could have been in Deacon's place. A sergeant had sought volunteers: one to go with a colonel to look at Japanese positions, the other to give blood. Rawls and his friend Deacon volunteered. As Rawls had the right blood type he gave blood while Deacon accompanied the colonel. Unfortunately, Deacon and the colonel came under fire from the Japanese and were killed by a mortar shell while sheltering.

The third incident was news of the Holocaust which made Rawls question how he could: "…pray and ask God to help me, or my family, or my country or any other cherished thing I cared about when God would not save millions of Jews from Hitler?"

Post-War Academic Life

Rawls was offered an officer position at the end of the war but declined. Having given up any thoughts of joining a seminary, he returned to Princeton in 1946 and after a year's fellowship at Cornell, completed his PhD at Princeton. While completing his thesis Rawls met Margaret Fox, his wife to be. They married in 1949 and, later, had four children, two boys and two girls.

Rawls taught at Princeton until 1952 when he received a Fulbright Fellowship to attend Oxford University. At Oxford he met and was influenced by HLA Hart, Isaiah Berlin, and Stuart Hampshire. Hart's influence in particular perhaps can be seen in Rawls' second published essay 'Two Concepts of Rules' (1955). Influenced by his time at Oxford, Rawls continued to develop his theory of political justice and he published widely with a flurry of articles on justice appearing between 1958 and 1969.

After his time at Oxford, Rawls obtained a faculty position at Cornell University. He was also a visiting professor at Harvard and a professor at MIT before finally becoming a permanent member of the philosophy department faculty at Harvard from 1962.

In the 1960s Rawls, perhaps influenced by his own memories of war, strongly criticized the Vietnam War. In particular, he opposed the 2-S deferment. This deferment allowed college students to avoid the conscription to focus on their studies but, in practice, it was misappropriated to enable children with wealthy backgrounds to avoid conscription. Rawls believed that this was not only unfair, but logically that a society would be less likely to engage in unjust wars if the children of political elite were on the front lines. In 1966, Rawls therefore introduced a controversial resolution to the Harvard faculty condemning the deferment.

Rawls retired in 1991 but continued to teach until he was unfortunately largely incapacitated in 1995 by the first in a series of strokes. Despite this, he continued to work, and with assistance he completed: a new introduction to *Political Liberalism* (1996, hereafter *PL*); the Idea of Public Reason Revisited; and most substantial of all his third book, *The Law of* Peoples (1999, hereafter *LP*). In addition, he participated in the editing of his collected papers and of three collections of his lectures. Not one to be idle in respect of causes he supported, in 1997, Rawls also joined five other philosophers in a brief to the US Supreme Court supporting a 'right to die.' The Court did not support a constitutional right to die, but nor did it prevent states from establishing laws that would establish such a right. Many supporters of physician-assisted suicide considered this a huge victory.

Rawls passed away at his home in Massachusetts in 2002.

Short Description of Major Works

Main Achievements

Although Rawls published articles and papers throughout his life, the focal point of Rawls' work is contained within three books. The first, *A Theory of Justice* (1971), sets out the basic principles of Rawls' theory of 'Justice as Fairness.' In 1999, Rawls issued a revised edition of *A Theory of Justice* (and all references to *TJ* hereafter shall refer to this revised edition) (and he later further summarized his modification of justice as fairness in *Justice as Fairness: A Restatement* (2001)). The second, *PL*, transfers justice as fairness from a metaphysical to political setting. The third, *LP*, applies Rawls' earlier work to global justice.

A Theory of Justice: Pre-Publication

Rawls is best known for his theory of 'Justice as Fairness.' Rawls began formulating his ideas of Justice as Fairness following the completion of his PhD, but it was not until 20 years later that he detailed his theory in *TJ*.

During that 20-year development period Rawls published many articles, and, in *TJ*, Rawls tried to coherently bring together some of those arguments. Accordingly, the first part of *TJ* elaborates on Rawls' earlier essays 'Justice as Fairness' (1958) (which set out the core of his argument of 'Justice as Fairness') and 'Distributive Justice: Some Addenda' (1968). The three chapters of the second part broadly correspond, respectively, to 'Constitutional Liberty' (1963), 'Distributive Justice' (1967) and 'Civil Disobedience' (1966) and the second chapter of last part covers subjects of 'The Sense of Justice' (1963). It is also worth mentioning two other essays that were important precursors to Rawls' Justice as Fairness. Rawls first began to develop his ideas of reflective equilibrium in his essay 'Outline of a Decision Procedure for Ethics' (1951), and in 'Two Concepts of Rules' (1955) he reframed utilitarianism as a theory specifically addressed to problems of political philosophy.

A Theory of Justice: In Context

Rawls developed his ideas for *TJ* during the 1950s, a time when welfare-state institutions were first introduced and liberals were seeking philosophical justification for their belief that social policies should not be driven by profit, but should be to the benefit of all. Concurrently, the concept of individual rights was becoming dominant. Against this background, Rawls theory was therefore unique in supplying both a commitment to individual rights, and an argument for social justice.

However, Rawls' aim in a *TJ* was to work out a conception of justice that provided an alternative to utilitarianism, which was then the predominant theory of moral and political philosophy. For Rawls, an account of the basic rights and liberties of citizens as free and equal persons was vital to any theory of democratic institutions, and utilitarianism was unable to deliver such an account.

Social Justice and Institutions

Utilitarianism is often interpreted as a complete moral philosophy. However, Rawls addresses a narrower conception of utilitarianism, utilitarianism as a theory of 'social justice.' Accordingly, the primary subject of justice for Rawls is the 'basic structure of society,' and he therefore seeks to evaluate whether the institutions that constitute the basic structure of society are just. Institutions for Rawls are the economic, political, and social systems or arrangements that distribute fundamental rights and duties (what Rawls calls 'primary social goods') and determine the division of advantages in society. Taken together institutions therefore define a citizen's rights and duties, thereby influencing their life plan and prospects. The basic structure is the primary subject of Rawls theory of justice because its effects are so profound.

'Original Position' and the 'Veil of Ignorance'

Traditional social contract theories were extremely unpopular at the start of Rawls' career. However, Rawls, a great admirer of Kant, realized that the sometimes hard-to-decipher concepts in Kant and Locke's writings could be revised as a new theory that could potentially challenge utilitarianism. Rawls therefore reincarnated the social contract as the thought experiment he called the 'original position.' The original position establishes a hypothetical scenario in which a group of equal participants are tasked with reaching an agreement (i.e., the social contract) about the basic structure of a society (and in particular the

principles assigning basic rights and duties and the division of social benefits), which they are, once an agreement has been reached, to occupy.

Rawls wanted the principles of justice to be fair to all citizens. To force participants to select only principles that would be fair to everyone, Rawls determined that participants in the original position would need to agree the principles from behind a 'veil of ignorance.' The intention of the veil of ignorance is to shroud the participants from the knowledge of the actual position they will occupy in society and what their particular interests and inclinations will be. By preventing participants from shaping the principles by reference to personal advantage, participants can only proceed on the basis of securing to the greatest possible degree fairness for all, including themselves. The result of the veil of ignorance is that each participant is equal and no one is able to design principles to favor his or her position. Rawls called this the 'perspective of eternity.' Rawls argued that in this perspective, it would be irrational for participants to propose any ideas that that are innately unjust, for example, racism and sexism.

The specific knowledge that Rawls envisages the veil of ignorance stripping from participants in the original position is their: position in society; class or social status; natural assets or abilities (e.g., intelligence and strength); personal conception of the 'good'; personal life plan; and psychological inclination. In addition, participants will not know the economic and political situation of their society, the level of civilization and culture attained by their society, or the generation to which they belong. The only knowledge the participants retain is that they possess certain attributes and capacities. For example, each participant will know that they have the capacity to construe, hold, and revise 'a conception of the good,' or life plan – even if they are not aware what the content of that good is. In addition each participant is aware that they have the ability to develop a sense of justice and will generally comply with it.

Principles of Justice

The majority of *TJ* is devoted to considering which principles of justice would be chosen by participants in the original position. Rawls believes the participants would take a low-risk approach, agreeing to principles that are fundamentally equal, and that would guarantee for all the highest possible minimum levels of freedom, wealth, and opportunity – even if this means lowering the overall or average levels. In this situation, Rawls is therefore adamant the principle of utility would not be chosen. Stressing the inherent selfishness of people, he believes participants would not agree to a principle that may require lesser life prospects for some if it results in a greater sum of advantages for others.

Instead, Rawls formulates two new principles of justice that he believes people in the original position would choose. The first "requires equality in the assignment of basic rights and duties, while the second holds that social and economic inequalities, for example inequalities of wealth and authority are just only if they result in compensating benefits for everyone and in particular for the least advantaged members of society."

The initial formulation of the first principle, sometimes referred to as the Liberty Principle or Equality Principle, establishes an equality in basic liberties for all citizens and it is expressed in *TJ* as:

Each person is to have an equal right to the most extensive total system of equal basic liberties compatible with a similar system of liberty for all.

For Rawls basic liberties tend toward civil and political rights, as examples he mentions political liberty (the right to vote and to be eligible for public office); freedom of speech and assembly; liberty of conscience and freedom of thought; freedom of the person along with the right to hold (personal) property (which is defined in terms of moral capacities and self-respect rather than a natural right of ownership); and freedom from arbitrary arrest and seizure as defined by the rule of law.

Rawls' aims for the second principle are to ensure that basic liberties are available to all and to ensure distributive justice. Accordingly, the focus of the second principle is the distribution of wealth and opportunity and the design of institutions. Like the first principle, Rawls reevaluated and revised the second principle throughout his work, but at its most basic, it consists of two subprinciples. The first, which aims to ensure that persons with comparable talents and motivations face similar life chances, is often referred to as 'The Fair Equality of Opportunity Principle,' the sometimes controversial second, the intention of which is to ensure that inequalities in society work to the benefit of the least advantaged, is the 'Difference Principle.' For Rawls the 'least advantaged' are those that are: (1) persons whose family and class origins are more disadvantaged than others; (2) persons whose natural endowments (as realized) permit them to fare less well; and (3) those whose fortune and luck in the course of life turn out to be disadvantaged.

The second principle is formulated in *TJ* as follows:

Social and economic inequalities are to be arranged so that they are both (1) to the greatest expected benefit of the least advantaged and (2) attached to offices and positions open to all under conditions of fair equality of opportunity.

Rawls stressed that the first and second principles are 'lexically' ordered. The first principle, of liberty, has priority over the second, while the second will always be prior to concerns of 'efficiency' or 'maximization of advantage' and the acceptance of inequality.

The choice of these principles presupposes that participants in the original position are rational. The priority of liberty is, for Rawls, the rational choice because it will benefit each participant by allowing him or her to attain their ultimate success, notwithstanding the parameters of their actual situation. In addition, the acceptance of inequality is also a consequence of the participants rational self-interest. For Rawls each participant aims individually for the best for themselves. Although they seek to ensure the best possible potential position for themselves, in light of the cautious and prudent psychology built into humans, they ensure there is a safeguard for those participants that unfortunately are dealt a hand of disadvantage. This demonstrates the operation of the 'maximin' principle (maximizing the position of the least advantaged) that threads throughout Rawls' writings.

Application of the Principles of Justice

Underlying Rawls' discussion of the principles of justice is his intention that these two principles will steer the design of the

institutions that comprise the basic structure of society. Rawls therefore delineates a four-stage sequence for the application of his principles. If followed, Rawls believes the resulting institutions will be just. The four stages in sequence are the following:

1. An enunciation of principles of justice from the original position.
2. A lifting of the veil of ignorance so that participants become aware of the general conditions of society, but not their own individual circumstances, in order that participants can devise a constitutional system that addresses, in accordance with the principles, the powers of government and rights and duties of citizens. Rawls stresses that this process must among other criteria address the existence of different, and possibly divergent, political viewpoints. However, in consideration of the priority of liberty, Rawls' contention is that the outcome will be a constitutional democracy.
3. The third stage is the legislative stage. Legislation should be drawn up in accordance with the principles of justice as well as constitutional procedures. Again legislators are required to act in light of general, and not personal, interests.
4. Finally, the laws and rules that have been legislated will be applied by judges and administrators – and will govern the actions of citizens generally. At this stage the veil of ignorance is removed completely.

Reflective Equilibrium

TJ also introduced Rawls' concept of 'reflective equilibrium,' and an approach to achieving a state of reflective equilibrium is used in *TJ* as a method for the justification (and to some extent construction) of the principles. Wenar describes reflective equilibrium as a state where "all of one's beliefs on all levels of generality agree perfectly with one another" and he further clarifies that "in reflective equilibrium one's abstract beliefs explain one's more general convictions which in turn explain one's specific judgments." In effect, Rawls' method of achieving a state of 'reflective equilibrium' is a technique for the deliberation and consideration of morality. At its center is a procedure of constant reevaluation, testing of principles against considered judgments, and vice versa.

Rawls' method of achieving reflective equilibrium can be summarized as follows, using justice as an example. First, a group of considered judgments about justice (generally based on secure intuitions) are identified. Attempts are then undertaken to explain, and justify, these judgments through the formulation of abstract principles of justice. Finally, any discrepancy between the principles and considered judgments is addressed. This could be either by modifying the principles or revising existing considered judgments (and for Rawls even judgments that are initially regarded as fixed are liable to revision).

Rawls believed that by going back and forth between these steps and constantly testing ideas, eventually abstract principles would be yielded that matched and explained considered judgments. The 'ideal state' achieved following this method was what Rawls termed reflective equilibrium, stating "it is an equilibrium because at last principles and judgments coincide; and it is reflective since it is clear what principles the judgments confirm and the premises of their derivation."

Political Liberalism: From the Metaphysical to the Political

After *TJ*, Rawls continued to work on his theory of justice as fairness, publishing more articles and revising extending and defending his theory. Rawls also began to reconsider some aspects of his theory and these reconsiderations initially appeared in a series of papers, the three most important are *Kantian Constructivism in Moral Theory* (1980), *Social Unity and Primary Goods* (1982), and *Justice as Fairness: Political not Metaphysical* (1985). Eventually, over 20 years after the publication of *TJ*, Rawls published his second book, *PL*.

Although the theory of justice as fairness remains at the heart of *PL*, Rawls refocuses the theory so that it (1) moves from a metaphysical to political sphere and (2) can be used as a means of coexistence by people who have different theories of the good. *PL* therefore converts the doctrine of justice as fairness presented in *TJ* into a political conception of justice. This reinterpretation of the theory is also continued in Rawls later, unfinished work Justice as Fairness: A Restatement (2001).

At the heart of *PL* is the question of stability and, more particularly, whether a society ordered by the two principles of justice as fairness can endure. Although Part III of *TJ* attempted to give an account of stability, Rawls came to view this account as defective and inconsistent with his theory as a whole and he recognized that the political conception offered in *TJ* had to be extended so that it worked even when faced with differing doctrines and conceptions of the good. In *PL*, Rawls therefore considers how it is possible for a just and stable society to endure, despite diverging philosophical, religious, and moral views held by citizens, what Rawls, borrowing from Cohen, calls 'reasonable pluralism.'

For Rawls, 'reasonable pluralism' is the existence of the various moral and metaphysical 'comprehensive doctrines' that characterize a society. These metaphysical comprehensive doctrines are the systems of beliefs that give life its meaning or value, for example, religious or philosophical doctrines. Although these doctrines can coexist, they are generally incompatible, with often insurmountable differences. The 'Reasonable' in reasonable pluralism refers to 'reasonable' comprehensive doctrines. For Rawls, a reasonable doctrine is one which (1) relies on the employment of practical and theoretical reason, (2) is conscious of its fallibility, and (3) is open to possibility of change.

In the context of reasonable pluralism, the legitimacy of any theory of social justice is, according to Rawls, dependent on whether it can serve as the focus of an 'overlapping consensus.' To fall within Rawls' concept of an 'overlapping consensus' the theory must therefore remain not only neutral between reasonable comprehensive doctrines, but also political, that is, nonmoral, freestanding, and independent of any comprehensive doctrine. Simultaneously, the theory must be acceptable to all in the political community and able to constitute a basis of their beliefs. Any legitimate theory therefore must be such that it can be accommodated within any comprehensive doctrine and acceptable to all.

Of course, for Rawls, Justice as Fairness was the single conception of social justice that could fit within all reasonable comprehensive doctrines and could serve as the focus of an overlapping consensus. To achieve this, some alterations to Justice as Fairness are rendered in *PL*. In particular, to ensure that Rawls' political conception of justice is free-standing (that is not derived from, or part of, any comprehensive doctrine), Rawls modifies his account of primary goods and his argument for the lexical ordering of the two principles. Importantly, Rawls also alters the principles of justice themselves. Although the first principle retains priority over the second, Rawls determined that in the new lexical ordering the first half of the second principle would have priority over the second half. The revised principles are therefore set out as follows:

1. Each person has an equal claim to a fully adequate scheme of equal basic rights and liberties, which scheme is compatible with the same scheme for all; and in this scheme the equal basic liberties, and only those liberties, are to be guaranteed their fair value.
2. Social and economic inequalities are to satisfy two conditions: first, they are to be attached to positions and offices open to all under conditions of fair equality of opportunity; second, they are to be to the greatest benefit of the least advantaged members of society.

The modifications are subtle but important. Most notably, Rawls switches the two parts of the second principle, so that the difference principle becomes subordinate to not only the first principle but also the condition of fair equality of opportunity.

The Law of Peoples: Global Justice and International Relations

Before LP, Rawls only briefly mentioned the application of his theory on a global basis: in *TJ*, he suggested the original position could be used to generate principles of global justice, in the same way it was used to generate the two principles of social justice. However, he made this comment in passing as a way of supplying some possible nonreligious grounds for conscientious refusal. Accordingly, there is no substantial indication as to what principles such a procedure would generate.

Following this, two significant attempts were made to apply the reasoning behind justice as fairness to global justice: Beitz's *Political Theory and International Relations* (1979) and Pogge's *Realising Rawls* (1989). Reaching similar conclusions, both argued that people from all states should be included in the original position. The participants in this global original position would then select principles of global justice in accordance with Rawls' theory of Justice as Fairness. Beitz and Pogge both argue that arguments in favor of the application of the difference principle in a state must be equally valid across states. Consequently, they advocate redistribution from wealthy and advantaged societies, to poor and less advantaged societies.

In *LP*, Rawls decided to address the problem of global justice and international relations. Rawls saw human rights as distinct from liberal rights and did not see it to be the role of liberal peoples to impose liberalism upon 'decent' societies. Many were surprised that Rawls did not therefore endorse Beitz and Pogge's conclusions and he did not apply the difference principle globally, nor endorse a global principle of distributive justice.

Instead, Rawls envisaged that there would be two conceptions of the original position. The first original position would take place separately in each state, as set out in *TJ*. Thereafter, Rawls envisaged that well-ordered societies (by which he meant states whose institutions respect the rights and interests of their citizens) would each send a representative to a 'global original position.' Participants in this global original position would still be subject to a veil of ignorance, except they would be aware that they were not representing the interests of all societies or all citizens but only well-ordered societies. Rawls believes this system would result in principles of global justice that commit to state autonomy rather than global redistribution. Although this account was a more accurate reflection of international affairs it divided Rawls' supporters, with some accusing Rawls of making unjustified compromises.

Lasting Impact/Influence

Rawls is often credited with single-handedly reviving the study of political philosophy the popularity of which, before his writing, was in steady decline. However, Rawls' influence is not limited to the spheres of political science or philosophy but crosses disciplinary lines receiving serious attention from legal scholars, economists, theologians and sociologists as well as political scientists and philosophers.

Although not all agree with Rawls' ideas, his contribution to the character and form of political philosophy has been lasting. Rawls inadvertently reframed the boundaries of political philosophy with debates today almost always formulated in Rawls' language. In addition, Rawls' conception of justice has generated a cornucopia of secondary literature, inspiring numerous academic debates, and different approaches. There are too many to mention here, but worthy of note is Nozick's *Anarchy, State and Utopia* (1974), in which Nozick argues against Rawls' theory of justice as fairness from a broadly libertarian point of view, promoting individual rights as an absolute standard, with primacy over any unwanted interference or other moral and political considerations; Dworkin's *Taking Rights Seriously* (1977) and Ackerman's *Social Justice in the Liberal State* (1980) which present an alternative libertarian egalitarian standpoint; Sandel's *Liberalism and the Limits of Justice* (1982), Walzer's *Spheres of Justice: A Defense of Pluralism and Equality* (1983), and MacIntrye's *After Virtue* (2007) all of which are inspiring communitarian-influenced critiques and/or rework Rawls' theories; Pateman's *The Sexual Contract* (1988) and Okin's *Justice Gender & The Family* (1989) which critique Rawls from a feminist's standpoint, and finally the influence of Rawl's seminal ideas can also be gleaned in Sen's *Inequality Re-examined* (1992) and Nussbaum's *Women and Human Development: The Capabilities Approach* (2000).

EDITOR IN CHIEF BIOGRAPHY

James D. Wright received his bachelor's degree in philosophy from Purdue University in 1969, a master's degree in sociology from the University of Wisconsin in 1970, and his PhD in sociology from Wisconsin in 1973. His first academic appointment was at the University of Massachusetts, Amherst, where he was promoted to Associate Professor in 1976 and to Full Professor in 1979. Most of his 15 years at Massachusetts were spent as Director, Associate Director, or Director of Research in the Social and Demographic Institute.

Wright left Massachusetts for Tulane University in New Orleans in 1988 where he served as the Charles and Leo Favrot Professor of Human Relations in Tulane's Department of Sociology. He also enjoyed a courtesy appointment in the Tulane School of Public Health, Department of Biostatistics and Epidemiology. He left Tulane in 2001 to become the Provost's Distinguished Research Professor of Sociology at the University of Central Florida. In 2003, he was named as the Director of the University's Institute for Social and Behavioral Sciences and in 2013, was designated as a UCF Pegasus Professor, the University's highest faculty honor.

Wright was the Editor in Chief of the scholarly journal *Social Science Research* from 1978 until 2014. His previous editing experience also includes a 20-year stint as editor of the Aldine de Gruyter book series *Social Institutions and Social Change*, two editions of the *Handbook of Survey Research* (Academic Press, 1983; Emerald Publishing, 2010), and service on the editorial boards of numerous journals. He is the author of 21 books and scholarly monographs on topics ranging from homelessness to research methods to NASCAR, and he has published more than 300 journal articles, book chapters, reviews, essays, and polemics. Wright lives with his wife Christine Stewart and their multiple dogs and cats in Winter Springs, Florida, where in his spare time he likes to cook fancy meals for large crowds.

PREFACE TO THE FIRST EDITION

Large and ambitious works such as the present Encyclopedia depend on countless instances of input, cooperation, and contextual support. Therefore, the editors in chief would like to express their gratitude to several institutions and individuals. Our most general thanks go to our respective home institutions, the Center for Advanced Study in the Behavioral Sciences, Stanford, and the Max Planck Institute for Human Development, Berlin. We are certain that without the effective infrastructures of these institutions and the rich collegial networks and intellectual climate they provide, implementing this Encyclopedia in such a short amount of time would not have been possible. In this context, we also need to mention that due to the administrative budgets provided to the editors in chief by the publisher, the financial strains on our home institutions were minimal. Such a situation may be a rarity in the modern world of scientific publishing where publishers often press scholars and institutions into taking on larger and larger shares of the publication enterprise.

Aside from the more than 4000 authors, our deepest thanks goes to the editors of the 39 sections, to whom we delegated many decisions at various stages, who were primarily responsible for developing the lists of articles and authors, and who stood as the main gatekeepers of scientific quality for the entries in their sections. As a group, the section editors displayed remarkable energy, intelligence, and tolerance for the inevitable frustrations of tending large numbers of authors over a long period of time. Because of the brevity of the acknowledgment of the main editorial coproducers here, we alert the reader to the list published as part of the front matter and the description of their extensive work we offer in the Introduction. We would also like to mention that one of our highly esteemed section editors, Franz Weinert, died unexpectedly during the last phases of his editorial work. For people who had the pleasure of knowing Franz Weinert, it comes as no surprise that he completed his editorial duties without ever complaining about the difficult health conditions he was facing. He was a gentleman and a distinguished scholar.

The International Advisors also gave wise counsel on several designated occasions, and a number of these scholars represented on the International Advisory Board took more initiative — always helpful — than we had originally asked. The International Advisory Board was particularly helpful in the process of choosing section editors. Some of its members assisted us ably as we attempted to make the Encyclopedia as international as possible and also in dealing with special problems that are part of a large project with close timelines. Thus, we remember a few occasions where members of the International Advisory Board helped us with their substantive and social competence to deal with matters of editorial disagreements. Because of the overall quality, collaborative spirit, and professional responsibility of our section editors, these events were rare indeed, but dealing with them required masterful and accelerated input. We appreciate the collegiality that members of the Board displayed when called upon in these special circumstances.

In addition, and as described in the Introduction, there was a host of esteemed colleagues who gave us advice on numerous questions such as author and editor selection, organizational matters, topics for entries, content and quality of selected articles, substantive and methodological niches to be covered, as well as last-minute author replacements. The number of such individuals is large indeed, and most likely, significantly larger than the list presented below. There were too many short, but nevertheless significant collaborative encounters that we likely did not deposit into our long-term memory or written documentation. We apologize for such oversights.

In this spirit, we appreciate the advice given in the three planning meetings in Stanford, Uppsala, and Dölln/Berlin by the following scholars: Peter Behrens, Burton Clark, Gordon Clark, Lorraine Daston, Meinolf Dierkes, Jean-Emile Gombert, Torsten Husén, Gérard Jorland, Ali Kazancigil, Wolfgang Klein, Gardner Lindzey, Renate

Mayntz, Andrew Pettigrew, Denis Phillips, Marc Richelle, Ursula M. Staudinger, Piotr Sztompka, Eskil Wadensjö, Björn Wittrock, and Robert Zajonc.

We would like to extend special thanks to Laura Stoker, who pinch-hit for Nelson Polsby (section editor for Political Science) who was unable to attend the meeting of section editors in April 1998; and to Linda Woodhead, Senior Lecturer in Religious Studies, Lancaster University, who assisted David Martin with editorial work at all phases for the section on Religious Studies.

We also acknowledge the help of scholars who advised Smelser and Baltes at the stage of pulling together the entry lists, proposing authors, and occasionally reviewing the content and quality of articles submitted.

Smelser thanks: Jeffrey Banks, Peter Bickel, Edgar Borgatta, Charles Camic, Jennifer Chatman, Jean Cohen, Michael Dear, Pierre Ducrey, Eckart Ehlers, Sylvie Faucheux, Steven Guteman, Frank Furstenberg, Helga Haftendorn, Peter Katzenstein, David Laibson, Stephan Lauritzen, Douglas McAdam, Eleanor Maccoby, Phyllis Mack, Cora Marrett, Douglas Massey, Donald Melnick, Harvey Molotch, Lincoln Moses, James Peacock, Trond Petersen, Andrew Pettigrew, Alejandro Portes, Matilda Riley, István Rév, John Roberts, Dorothy Ross, Rob Sampson, Fritz Scharpf, Melvin Seeman, James Short, Fritz Stern, Carol Swain, Ann Swidler, Ken'ichi Tominaga, Charles Tilly, Wolfgang van den Daele, Sidney Verba, Margaret Weir, Thomas Weisner, and Jennifer Wolch.

Baltes is very grateful to: Nancy Andreasen, Gerhard Arminger, André-Jean Arnaud, Jens Asendorpf, Jan Assmann, Margret Baltes (deceased), Jürgen Baumert, Peter Behrens, Manfred Bierwisch, Niels Birbaumer, Peter Bloßfeld, Walter Borman, Robert F. Boruch, Mark Bouton, Michael Bratmann, David Buss, Shelley Chaiken, Lorraine Daston, Juan Delius, Marvin Dunnette, Georg Elwert, Helmut Fend, Hans Fischer, Peter Frensch, Alexandra M. Freund, Dieter Frey, Jochen Frowein, Gerd Gigerenzer, Snait Gissis, Peter Gollwitzer, Ian G. Gotlib, David Gyori, Heinz Häfner, Helga Haftendorn, Giyoo Hatano, Adrienne Héritier, Theo Herrmann, Otfried Höffe, Ludger Honnefelder, Paul Hoyningen-Huene, James Huang, Günther Kaiser, Heidi Keller, Martina Kessel, Gábor Klaniczay, Wolf-Hagen Krauth, Achim Leschinsky, Karen Li, Shu-Chen Li, Ulman Lindenberger, Elizabeth Loftus, Gerd Lüer, Ingrid Lunt, Hans J. Markowitsch, Laura Martignon, Randolf Menzel, Dietmar Mieth, Susan Mineka, Setsuo Miyazawa, John R. Nesselroade, Claus Offe, Vimla Patel, Meinrad Perrez, Rosa Lynn Pinkus, Robert Plomin, Neville Postlethwaite, Thomas Rentsch, István Rév, Peter Roeder, Richard Rorty, Hubert Rottleuthner, Peter Schäfer, Heinz Schuler, Norbert Schwarz, Richard J. Shavelson, Joan E. Sieber, Burton Singer, Wolf Singer, Edward Smith, Hans Spada, Günter Spur, Rolf Steyer, Michael Stolleis, José Juan Toharia, LeRoy B. Walters, Elke U. Weber, Peter Weingart, and Reiner Wimmer.

There was one more group that played a special role in the editorial review (see also Introduction). Baltes was assisted by a team of colleagues who provided expert input to the section editors and to him during final review: Gregor Bachmann, Alexandra M. Freund, Judith Glück, Wolfgang Klein, Olaf Köller, Shu-Chen Li, Ulman Lindenberger, Ursula M. Staudinger, and Christine Windbichler. Their expertise in helping us to ensure quality is gratefully acknowledged.

The day-to-day organizational work of the editors in chief occurred at their respective research centers — the Center for Advanced Study in the Behavioral Sciences and the Max Planck Institute for Human Development in Berlin. Smelser singles out Julie Schumacher, his main assistant in the project, for her organization of the meeting of section editors, and her superb coordination of the flow of correspondence and manuscripts over several years. She remained firm when the rest of us were faltering, and displayed the greatest efficiency, intelligence, and good cheer. Smelser also relied on periodic help from Leslie Lindzey, Kathleen Much, Jane Kolmodin, and Anne Carpinetti. Michelle Williams of the University of California, Berkeley, served as his main editorial assistant for nearly 2 years, going over all entry manuscripts from the standpoint of readability, and carrying a great part of the cross-referencing work; her judgment was always the best, and Smelser is forever indebted to her.

At the Max Planck Institute for Human Development, and aside from Julia Delius (see below), Baltes expresses his deeply felt thanks to the main secretarial staff in his office (Helga Kaiser, Romy Schlüter, Conor Toomey) who during the preparation of this Encyclopedia took on larger shares of responsibilities for other projects and occasionally helped out when the editorial office was overloaded. More directly involved in the day-to-day operation of the Encyclopedia was Penny Motley, who efficiently functioned as project secretary during the planning phase. During the main phases of the project, it was Yvonne Bennett who was responsible for secretarial and organizational matters. She deserves much applause for her superb and efficient help in the day-to-day running of the editorial office, making sure that all manuscripts and proofs were processed quickly, and also for assisting with the organization of various meetings. Not least, Baltes thanks the administrative office of the Max Planck Institute, and there especially Nina Körner and Karin Marschlich, for their competent work in managing the project budget, as well as Sabine Norfolk who handled most of the numerous fax

transmissions with ever present smiles and friendliness. Finally, in the Berlin editorial office, thanks are also due to Susannah Goss for her excellent work in translating individual articles into English.

Individual section editors wish to thank the following scholars who gave them substantive advice in their work: Richard Abel, Itty Abraham, John Ambler, Karen Anderson, Mitchell Ash, Alan Baddeley, Boris Baltes, Manfred Bierwisch, Michael Bittman, Sophie Bowlby, John Carson, Shelly Chaiken, Roger Chartier, François Chazel, Stewart Clegg, Carol Colby, Philip Converse, James Curran, Jerry Davis, Natalie Z. Davis, Peter Dear, Juan Delius, Michael Dennis, Josh DeWind, Sherry Diamond, Elsa Dixler, Georg Elwert, Howard Erlanger, Drew Faust, Malcolm Feeley, Nancy Folbre, Michael Frese, Angela Friederici, Lawrence Friedman, Bryant Garth; Victor Ginsburgh; Marcial Godoy, Frances Goldscheider, Calvin Goldscheider, John H. Goldthorpe, Reginald Golledge, William Graziano, Stephen Gudeman, Mauro Guillen, Doug Guthrie, John Hagan, Eric Hershberg, Steve Heydemann, Stephen Hilgartner, Judith Howard, William Howell, Jill Jaeger, Bob Kagan, Joe Karaganis, Roger E. Kasperson, Ronald Kassimir, Robert W. Kates, Wolfgang Klein, Hans-Dieter Klingemann, Bert Kritzer, Kay Levine, Steven Lukes, Michael Lynch, Akin Mabogunje, Stuart Macaulay, Donald MacKenzie, David Magnusson, Michael McCann, Sally Merry, Peter Meusburger, Sieglinde Modell, John Monahan, Kevin Moore, Gerda Neyer, Hiroyuki Ninomiya, Jodi O'Brien, Eva Oesterberg, Mark Osiel, James L. Peacock, Susan Phillips, Trevor Pinch, Wolfgang Prinz, Sheri Ranis, Harry Reis, Estevao C. de Rezende Martins, Marc Richelle, Leila Rupp, Gigi Santow, Austin Sarat, Simon Schaffer, Linda Scott, Tim Shallice, Seteney Shami, Ronen Shamir, Susan Silbey, Wolf Singer, Sheila Slaughter, Gerhard Strube, Ursula M. Staudinger, J. Stengers, Stephen M. Stigler, Michael Stolleis, Mark Suchman, Denis Szabo, Verta Taylor, Ashley Timmer, David Trubek, Leslie Ungerleider, Don Van Arsdol, Jakob Vogel, Rita Vörg, Judy Wajcman, Mary Wegner, Wlodzimierz Wesolowski, Steve Wheatley, Björn Wittrock, and Vincent Wright (deceased).

Section editors also thanked the following persons for their research assistance: Pamela Anderson, Susan Augir, Anja Berkes, Chantale Bousquet, Aida Bilalbegović, John Clark, Susanne Dengler, Kathrine Derbyshire, Annie Devinant, Casey B.K. Dominguez, Barbara Dorney, Elizabeth Dowling, Tracey L. Dowdeswell, Carolyn Dymond, Debbie Fitch, Susannah Goss, Verhan Henderson, Andrew Hostetler, Gudrun Klein, Heike Kubisch, Angie Lam, Ellen Lee, Valerie Lenhart, Kay Levine, Allison Lynn, Helena Maravilla, Carol B. Marley, Marion Maruschak, Michael McClelland, Rhonda Moats, Birgit Möller, Katja Neumann, Linda Peterson, Justin Powell, Paul Price, Xandra Rarden, Chris Reiter, Deborah Sadowski, Heidi Schulze, Heidi Sestrich, Keith Smith, Judith Thompson, Karen Varilla, Stuart Vizard, Danelle Winship.

It is difficult to single out one person as especially helpful. Despite the risks involved, we would like to highlight one person (see also Introduction). As shown in the front matter, beginning in the second year of the planning phase, Julia Delius served as our scientific editorial assistant. For our internal process of editorial review and management, Julia Delius was the mastermind of editorial coordination. Her work was simply outstanding.

Finally, we express our thanks to several individuals at Elsevier publishers whose work was both essential and helpful to us throughout. Barbara Barrett started the ball rolling for the entire Encyclopedia project, and was a master at negotiating out the fundamental arrangements at the beginning. Geraldine Billingham, as executive editor, also played an important role in the development of the project, as well as carrying the heavy responsibility for ensuring that all the financial and operational aspects of the project were realized. She executed this work with directness, skill, and tact. Angela Greenwell coordinated the editorial process with dexterity, calmness, and good judgment. Three persons were responsible for monitoring the progress of entries from Elsevier's side: Michael Lax for a time at the beginning; Jayne Harrison, who carried an overwhelming load of manuscripts month after month, and Helen Collins, who was responsible for the equally demanding job of shepherding the manuscripts through the entire production process. Ruth Glynn skillfully and imaginatively masterminded the development of the electronic version within Science Direct. We know how much the success of the Encyclopedia has depended on these individuals and their staffs, and our appreciation and admiration is here recorded.

Our expressions of gratitude and respect for the authors, section editors, reviewers, counselors, and editorial team, however, are not meant to distract from our own responsibilities as editors in chief. Let us hasten to add, therefore, that those whom we acknowledge deserve most of the credit but little of the blame for whatever shortcomings remain.

Neil J. Smelser
Paul B. Baltes
Palo Alto and Berlin
June 2001

INTRODUCTION

Alan Sica's article in this encyclopedia observes, "The urge to systematize and rationalize both common and esoteric knowledge has been strongly and continuously in evidence for at least 2400 years in the West" (Sica, 2015). Sica dates the origins of this urge to Plato's nephew Speusippus, who took up the challenge of Plato's call for an *encyclopedia* (from Greek words meaning 'general education'), and traces the urge though Pliny the Elder, Vincent of Beauvois, Francis Bacon, Denis Diderot, and a great many others. Today, an encyclopedia is simply a self-contained reference work "with two aims: to include up-to-date knowledge about a particular discipline or group of disciplines and to make this knowledge conveniently accessible" (Smelser and Baltes, 2001). Such are the aspirations of the present work.

Histories of the concept of an encyclopedia are widely available and need not occupy us here. Those interested in where the *International Encyclopedia of the Social and Behavioral Sciences* (IESBS) fits into the long history of encyclopedias will do well to consult the Sica article quoted above or the Smelser–Baltes 'Introduction' to the first edition of this work.

This is the second edition (2/e) of the IESBS. Elsewhere, I acknowledge my immense debt to the editors of the first edition, Dr Neil Smelser and Dr Paul Baltes. Without their perspective and template to follow in assembling the second edition, this version would have scarcely been possible. The very thought of an encyclopedia covering *all* the social and behavioral sciences, one that drew on scholars from *all* corners of the globe, is itself so audacious that one would hesitate even to begin without a pretty detailed road map to the terrain.

On the occasion of the publication of Robert E.L. Faris's widely acclaimed *Handbook of Modern Sociology*, Joseph Gittler was moved to ask, "With the plethora of new handbooks, reviews, and compendia in sociology, one wonders whether there is a need for yet another one." That question was posed almost 50 years ago; the ensuing half-century has been marked, as Sica says, by "an avalanche of reference materials the likes of which had never been seen in libraries prior to about 2000." So readers and critics are within their rights to ask: Why a second edition? Why now?

The first edition (1/e) was reviewed in *Contemporary Psychology* as "the largest corpus of knowledge about the social and behavioral sciences in existence" (Park, 2004). According to readily available data sources, IESBS 1/e has been cited nearly 6000 times in subsequent scholarly literature and has an h-index ($h = 24$) that would be the envy of many full professors. Citations are only one measure of impact, of course, and probably not the most important measure for a basic reference work intended more for students and a general audience than for practicing professionals. In addition to the thousands of scholarly citations, items from IESBS 1/e were 'hit' almost two *million* times on Science Direct between online publication in November 2002 and August 2014 — two million instances where IESBS 1/e was likely consulted as a basic reference source, to get quickly up to speed in a new area of research or to provide background for a paper or project, or just to satisfy a reader's curiosity. The first edition, in short, emerged soon after publication as a go-to reference work throughout the social and behavioral sciences. Michael Shanahan referred to the first edition as "the atomic bomb of reference works." It was thus an easy conclusion that the work had sufficient value to keep it alive and current.

In reading selected articles from the first edition, however, I was taken aback by how much and how quickly they had aged. The first articles I looked at were those pertinent to my own areas of research and in nearly every case, there was important recent work that I felt needed to be discussed. With the assistance of colleagues in other areas of the social and behavioral sciences, it became obvious that this was a general problem. To be sure, much of the material in 1/e has enduring value; indeed, roughly half the articles in 2/e are updated and revised items from the first edition. Still, it is sobering to realize just how quickly the frontiers of social science

knowledge shift and thus how quickly a basic reference source becomes dated. I am certain there are articles in the current edition that are already in need of some updating.

Smelser and Baltes enumerated six criteria that guided their decisions about what to include and what to leave out. The criteria are as follows:

1. secure knowledge, realizing that security of knowledge is a dynamic and relative term,
2. knowledge with balance and comprehensiveness,
3. knowledge that is integrative rather than fragmented,
4. knowledge that places the evidence into historical and theoretical context,
5. knowledge that highlights connections between topics and fields, and
6. knowledge that combines, where possible, theory and practice.

I would like to say I have followed these same criteria in determining the content of 2/e, but all six criteria have proved problematic in one or another way and thus deserve some comment in light of the present work:

1. What is secure knowledge today is apt to be recognized as wrong tomorrow. Many of our requests for updates to 1/e articles generated some response to the effect, "All of this is completely obsolete. We need to write a new entry from scratch." One would expect this to be true of areas of research such as behavioral genetics, say, or cognitive neuroscience or other fast-moving scientific fields, but it also turns out to be true of archaeology, history, and philosophy. The leading edge of research in *every* discipline threatens received wisdom; those who content themselves with received wisdom ('secure knowledge') will quickly find themselves behind the times. So our charge to authors was to focus less on the 'secure knowledge' in their respective fields and more on the cutting edge — the new perspectives, methods, findings, and issues that will animate social and behavioral science research in the coming decade.
2. Throughout the social sciences, the distinction between theory and ideology is sometimes difficult to discern, and so too the distinction between applied research and community or political activism. We need not invoke Max Weber's conclusions about the impossibility of a truly value-free social science to understand that ideological undertones and political preferences can often be detected in social science research work; sometimes, they are quite explicit. Nor is it much of a surprise to learn that many social scientists struggle, not always successfully, to distinguish between what they want the world to be and what the world in fact is. Such struggles are part of the process by which knowledge develops and are thus in evidence in many of the 2/e articles. It would be unwise to enforce by editorial fiat a consensus on issues that the social sciences themselves have yet to resolve.
3. The fragmentation of knowledge *across* disciplines is far more serious that the fragmentation of knowledge *within* them, although the latter is a problem as well. Many well-informed sociologists, for example, take pride in reading widely and can speak with some authority about what is going on in the field, even in areas of sociology that do not directly concern them. I assume this is also true of the other social and behavioral science disciplines and areas. But rare is the sociologist who is cognizant of work being done, say, in social geography *even when*, as is often the case, the fundamental problems, theoretical issues, and methodological approaches are similar. This is a widespread problem across the disciplines: The evolutionary psychologists do not know as much as they should about what the anthropologists are doing; the economists ignore a lot of pertinent work in sociology and political science; etc. For better or worse, disciplinary differentiation is an inherent element in the process of knowledge development and discovery, so this is a reality to be faced, not a problem to be solved. We dealt with this reality mainly in two ways: (1) Authors were encouraged wherever possible to think across rather than strictly within their disciplines. (2) Calling relevant work done in other disciplines to the reader's attention was a guiding principle for the choice of cross-references for each article.
4. Social-constructionist theories of knowledge would argue that knowledge does not become knowledge until it is placed in historical, cultural, social, political, and theoretical context. As put very simply and succinctly in the opening line of the famous text by Berger and Luckmann, "reality is socially constructed" (1966: 1). This is no less true of social science knowledge than knowledge in any other realm. Unfortunately, a great deal of what we think of as social science knowledge is based on biased samples of WEIRD people — that is, Western, Educated, Industrialized, Rich, and Democratic (Henrich et al., 2010). (The same point has, of course, been made by many others.) The WEIRD, thus defined, represent a rather exotic minority group judged by world standards, and the challenge for IESBS 2/e was therefore twofold: (1) to recruit non-WEIRD editors and authors where possible; and (2) to persuade all authors to incorporate comparative, cross-cultural, and

international themes and perspectives wherever it was possible to do so. This effort was more effective in some sections than in others. Moving away from nation-specific literature, themes, and results to a truly *international* (the I in IESBS) account of the social and behavioral sciences was an ever-present *desideratum* in my discussions with editors and authors.

Alas, an emphasis on cross-culturalism often brings to light that everything, or nearly everything, seems to vary by culture, subgroup, ethnicity or nation, and at that point the question arises whether social science generalization is even possible. Are there universals that cross all social groupings? Or does social science dissolve into a mist of group-specific particularities that adduce no general principles? That hardly seems desirable. Yet myopic and ethnocentric fixations on one's own society or culture are scarcely to be encouraged either.

The worst offenders in this regard tend to be social scientists from the USA (and from the West more generally), who, of course, also comprise the largest share of editors and authors for IESBS 2/e. True, as with greenhouse gases, the USA (and the West) also produce the largest share of the world's science, social and otherwise, and so it is inevitable that they also represent the largest share of IESBS 2/e contributors. The Swedish social anthropologist Ulf Hannerz wrote about this very issue in his marvelous essay, "Editing Anthropology" (Hannerz, 2010). Hannerz quotes a Canadian anthropologist who said of the "neighborly presence" of US anthropology that it was like being "in bed with the elephant." The same is true of most or all of the disciplines covered in this work. But then in a passage remarkable for both its insight and its generosity, Hannerz remarks, "No doubt tensions and conflicts may arise out of this situation, but perhaps it is better to understand that the elephant cannot help being an elephant, and that it makes sense for it, in its habitat, to behave in elephantine ways. A well-trained elephant, too, can do a lot of good, such as in carrying heavy loads." So if the elephant that is Western social and behavioral science has been pressed to carry the heavier load in these pages, that is, the price to be paid for being an elephant in the first place.

The larger issue here is that the social and behavioral sciences, which were largely birthed in the West, in Europe and the United States, mainly address a trans-Atlantic scientific dialogue, a dialogue that is carried out almost exclusively in English. Indeed, throughout much of the world, a scientist's stature is indexed in part by his or her success in publishing in English. Publications in the native language are simply *assumed* to be inferior. The main exceptions, tellingly, are French and German social scientists whose native-language publications are valorized. A Dutch or Portuguese or Hungarian social scientist who only published in the native language would be seriously punished in merit and tenure reviews. Elsevier's citation database Scopus *requires* English-language abstracts before a journal will even be considered for inclusion. And English (with American spellings) is likewise the official language of this encyclopedia. No resources were made available to get articles submitted in other languages translated (although several such articles were submitted). Inevitably, this biases the encyclopedia's coverage in favor of social science addressed to the trans-Atlantic dialogue. Consequently, a great deal of excellent social science published in Spanish, or Mandarin, or Farsi, or any of the other world languages, is overlooked.

That said, steps were taken to improve the internationalism of the encyclopedia's coverage throughout the 4 years of its development. To begin, I sought area and section editors from around the globe and urged them whenever possible to seek international (vs strictly Western) authors. Articles were often returned to their authors with explicit instructions to add international coverage. And when all efforts failed and we ended up with articles that were unmistakably restricted to a single nation in their coverage (frequently but not always, this was the US), I indicated the national focus in the article subtitle. Still, a great deal more WEIRD social and behavioral science remains in these pages than would be desirable in an *international* encyclopedia. In a later section, I give the national breakdown of everyone involved in this project.

5. An encyclopedia that "highlights connections between topics and fields" is easier to envision than to accomplish. Criterion (3) above speaks to the disciplinary fragmentation of our social science knowledge. William Easterly, the NYU economist, has written about the 'tyranny of experts' but the tyranny of the disciplines is an equal problem, a tyranny sanctified by the very academic structure of the modern university, where the separate and often warring colleges are each comprised of assorted departments, the latter representing basic academic disciplines. Interdisciplinary programs are almost invariably relegated to various centers, institutes, or specialized research laboratories — in short, to the periphery of the university's power structure. And while everyone *says* they want to encourage multi- and interdisciplinarity, very little is done to make that happen. Instead, departments remain as the fundamental unit of academic organization.

   Hortatory admonitions to editors and authors have made IESBS 2/e somewhat more interdisciplinary than its several predecessors, but in the end, the disciplinary emphasis in many of our articles would be hard

to overlook. Still, there are many sections of the work that were clearly developed with interdisciplinarity in mind and in which one finds interdisciplinary social science at its current best: environmental and ecological sciences; health; life course; sexuality; GLBT studies; public policy; evolutionary sciences; war, peace, violence, and conflict; and genetics, behavior, history, and society are a few sections that come immediately to mind.

I am particularly pleased with the extensive coverage given in 2/e to the interactions between the biological and social sciences. Harry Whitaker once remarked in a private e-mail that "we are all witnesses to the marriage of biology and the social sciences." Many of the articles found here are offspring of that marriage. And those articles leave little doubt that the future offspring of this marriage will be among the most exciting and insightful social science products of the coming decade.

The social sciences once resisted everything biological as rank reductionism; in addition, the social scientists have always feared that a mature and complete biology would eventually drive us out of business. Articles included in IESBS 2/e make it clear that 'nature' versus 'nurture' was the wrong question from the very beginning, that what we need to understand is how biological inheritance and social and cultural forces *interact* to produce individual and collective outcomes. This is where a lot of the interesting action in the social sciences is going to be in the coming years.

6. The coverage of the practical or applied sides of the various disciplines has been increased in this edition, so the applied content of 2/e certainly exceeds that of its predecessor. New to this edition is the entire section on applied social and behavioral sciences; also new is our large section on social work and the separate section on applied, industrial and organizational psychology. But as Sara Strickhouser and I say in our article on the history of applied social research, "The history of 'applied social science' is indeed the history of the social sciences themselves" (Strickhouser and Wright, 2015). All of the social sciences in their modern form were birthed in the post-Enlightenment effort to understand why people, their institutions and society as a whole were as they were — why greed was more visible than generosity, why oppression was more common than freedom, why inequalities of various sorts characterized every social institution. To the founders of the disciplines, the modern distinction between basic and applied scientific concerns would have seemed meaningless, as indeed it was.

The Planning Phase and Editorial Structure

Elsevier's original acquisitions editor for this project, Scott Bentley, discussed the broad outlines of our attack on IESBS 2/e with me in a series of phone calls in the early months of 2010. By May 2010, certain of these outlines had come into sharp relief. There would be a single editor in chief with a tier of 'responsible lieutenants' to assist. These lieutenants started out as advisory editors but soon morphed into the 10 area editors in the final editorial structure. Each area editor would in turn oversee various sections and each section would have its own editor or editors. The original plan was that the area editors would each be responsible for approximately 400 articles and each section editor responsible for about 100 articles, so that no one would have an excessive amount of work compared to everyone else. In the end, however, some sections required more articles and others fewer, so the areas vary from fewer than 300 to more than 600 articles, and the sections vary from fewer than 30 articles to well more than 200.

Prior to my first discussions with Scott Bentley, Elsevier had commissioned about 20 'market surveys,' roughly half from professional librarians and the other half from academics, each focused on 'what was right and what was wrong' with the first edition. The most insistent demand that surfaced was for a fully electronic, computer-searchable work either in addition to or instead of a print version. In the end, both an e-version and a print version are being made available. But there were also consistent concerns expressed about spotty coverage of some areas: no coverage of social work to speak of; inadequate coverage of accounting, marketing, and business; no separate section of criminology; haphazard coverage of applied topics and concerns; and so on. And there were the predictable concerns about undue Western domination of the work.

Working from the 1/e Table of Contents and this stack of 20 surveys, I tinkered for a few months with how best to expand coverage to address the concerns our reviewers had expressed; the result was (more or less) the editorial structure shown elsewhere in the front matter of this work. Thus, the 53 sections of 2/e are basically the 39 sections of the first edition plus sections that were added to cover important emerging areas of research interest (e.g., gay, lesbian, bisexual, and transsexual studies) or to provide deeper coverage of disciplines and subdisciplines that the first edition treated lightly if at all (applied social and behavioral sciences, social work). A

few of the first edition sections were eliminated entirely: specifically, integrative concepts and issues (something of a catch-all category for 1/e articles that were highly interdisciplinary or simply did not fit anywhere else) and gender studies (gender is now so thoroughly integrated into the research and thinking of all the social and behavioral science disciplines and subdisciplines that a separate section was unnecessary and somewhat retrograde). Others were altered or expanded in significant ways (organizational and management studies, for example, became the second edition section on management, organizations, business, marketing and finance; expressive forms evolved into the 2/e section on culture and the arts; linguistics was subdivided into three separate sections; etc.) And some subdisciplinary areas that were part of other sections in the first edition were given their own sections in the second (life course studies; sexuality; criminology; labor studies; and war, peace, violence, and conflict are the most prominent examples), just to ensure adequate coverage.

The Introduction to 1/e (Smelser and Baltes, 2001) discusses at great length the intellectual architecture of the first edition and its evolution; the agonizing decisions about rules for the biographical articles; whether to organize the work by discipline, by concept, by an a priori taxonomy of social science knowledge, or in some other manner; and related structural matters. What resulted in 1/e was something of a hybrid model with some sections clearly representing specific disciplines, others representing 'overarching topics,' still others representing 'intersecting fields,' and so on. My task was far less challenging: I thought the architecture of the first edition served its purposes admirably and so I adopted it wholesale for the second edition, with the small modifications noted above.

While each of the 53 sections of 2/e has some more or less obvious justifying logic or substantive or disciplinary coherence, their arrangement into the 10 areas of the second edition does not. As already indicated, decisions about what sections to include and exclude were made very early in the development of the second edition, based on what was in the first edition, what Elsevier's marketing surveys suggested as significant lacunae, and my own sense of things. The arrangement of the sections into areas came later and was dictated largely by the interests and expertise of those who had been persuaded to sign onto the enterprise. Thus, all the Linguistics sections are in Area Five along with the cognitive and neuroscience sections because Harry Whitaker at Northern Michigan University had been a linguist first, a neuroscientist second, and a historian of psychology third. Likewise, Area Eight contains its seemingly chaotic hodgepodge of evolutionary sciences, genetics, religious studies, science and technology studies, and law because these happen to be the fields of interest of the redoubtable Barbara Prainsack of King's College, London, whose editorial talents are as deep as her interests are broad. Simplifying only slightly, section editors were chosen for their substantive expertise in particular areas of research (as well as their international or cultural 'range'); the plan was that section editors would review each of their articles for completeness of coverage, currency, fairness, and the like. In contrast, area editors were chosen for their breadth of interest and knowledge spanning multiple sections – people who by nature, experience, and training would be good at seeing the big picture. The role of the area editors was to assure that the articles were at least modestly international and interdisciplinary and formed some sort of coherent whole.

As laid out in an early e-mail to one of the area editors, "In my mind, Advisory [Area] Editors are generalists and Section Editors are content specialists. The Section Editors need to bring breadth of knowledge to their responsibilities, of course, but the primary job requirement is expert understanding of the particular field or section. We need section editors who can commission pieces that adequately review past developments in the subject area, but who can also shape their portfolios to identify major unanswered questions and new research developments." This was the general model followed throughout the recruitment process.

The approach just sketched inevitably left a residual area made of up sections that none of the other area editors were willing or able to claim. That proved to be Area Ten. A very large number of scholars from various disciplines and world regions were approached about serving as the Area Ten Editor. All demurred until I approached Martin Bulmer of the University of Surrey, who served the project for about a year but was unable to continue and subsequently left the Board. So for the final year of the project, the editing of Area Ten was done mainly by me.

The online subject classification for IESBS 1/e did not correspond precisely to the sections of the first edition; the subject classifications listed articles by broad general topic regardless of which 1/e section developed them. So for the first year or so, my assistants and I labored to assign every 1/e topic to one of the 53 2/e sections. With 53 sections to populate with articles and about 4000 articles to classify, the process of assigning articles to unique sections occupied huge amounts of time and generated endlessly complicated spreadsheets. (After about a year of this, a document surfaced in the Elsevier archives that showed exactly where each 1/e article had originated.)

Along with populating the 2/e sections with articles, searching for area and section editors occupied a major part of the early going. The original idea was to identify the 10 area editors first and then enlist them in the

search for their section editors, but in fact, these processes were simultaneous and were about half-completed when the two planning meetings were held: the first in San Diego on 19 and 20 May 2011; the second in London on 5–7 June 2011. Although not part of the plan, the first meeting was mostly attended by area editors and the second, by section editors.

The agenda for both meetings was largely identical: achieve clarity on the respective roles of the various editors; solicit advice on filling the unfilled editorial slots; get buy-in on the project *mantra* (internationalism, interdisciplinarity, inclusiveness!); explain the relationship between the first and second editions (e.g., that all 1/e authors would be offered the opportunity to update their articles); explain the process of assigning articles to sections; and the like. In almost all cases, consensus was quickly forthcoming.

The largest substantive change in the second edition is the treatment of psychology. (Whether measured by students, practitioners, professors or programs, psychology is the largest of the social and behavioral sciences.) In the first edition, the whole of psychology was contained within four large sections: clinical and applied psychology; developmental, social, personality, and motivational psychology; cognitive psychology and cognitive science; and behavioral and cognitive neuroscience. Cognitive science and neuroscience are, of course, rapidly growing sectors of the psychological discipline and it seemed appropriate to devote an entire area of the second edition to them. This area contained seven separate sections (three of them devoted to linguistics). And the 'softer' psychological sciences were placed in a separate area comprised of eight sections (including psychiatry and social work). These changes were made to assure that 2/e had adequate coverage of the entire psychological enterprise (a concern that was raised in some of the reviews of 1/e).

The structure of the editorial team was developed to serve two purposes: first, to divide up the labor into manageable parts; and secondly, to assure that every article in the final product would be reviewed by at least three scholars: the respective section editor, area editor, and the editor in chief. Since we were all aware of one another's identities throughout, the review process was not blinded, but every article in this work has been thoroughly peer-reviewed and vetted. In many cases, these articles have been through four, five, six, or even more revisions before being accepted for inclusion in the work.

Recruiting Editors and Authors

IESBS 2/e faced two different recruiting tasks: recruiting editors and recruiting authors. As indicated elsewhere, the original plan was that I would recruit area editors largely from my own personal networks and they in turn would recruit their section editors. In practice, the process was much more convoluted. First off, many of my 'first choice' candidates were hesitant to involve themselves in such a daunting and ambitious project. In some cases, an initial agreement to come aboard was followed a few weeks or months later by withdrawal as the true scope of work came into sharper focus. Some people that I tried to recruit as area editors demurred but agreed to serve as section editors; in other cases, candidates for area editors were nominated by section editors. In a couple of cases, there was a complete team of section editors prior to the successful recruitment of a corresponding area editor. And so on. The process of assembling an editorial team for the project was by no means linear.

Personal networks – mine and those of the people I persuaded to sign on – were the largest single source of ideas for other editors, by far. But personal networks tend to follow disciplinary and national lines and become rather quickly exhausted. In selecting both editors and authors, it was of course essential that all relevant perspectives be covered and that the breadth of fields was adequately represented. So other sources of ideas were tapped: the expertise of the Major Reference Works team at Elsevier; editorial boards of leading journals in the respective fields; Google Scholar citation counts; the knowledge and networks of people who had been involved in preparing the first edition – basically, anywhere names of top scholars in particular areas could be located. I did not keep systematic track of the number of people approached, much less of the outcomes; but in reviewing my e-mail archives from the early period of the project, I probably asked (on average) somewhere between six and eight prospects before I found someone to agree (an average that was highly variable across the areas and sections).

In the initial plan, area editors would recruit their own section editors and the section editors would in turn recruit their own authors, but the reality was again different. Inevitably, my negotiations with prospective editors (both types) would often result in a declination of the editorial role but an offer to write an article on a particular topic (or topics), offers I readily accepted. So in some cases, I had committed authors of particular articles well before I had the corresponding section or area editor in place. And many of the section editors likewise leaned on their area editors and on me for author suggestions, contacts, and outreach. So all the editors

were involved in locating willing authors (and not coincidentally, in making suggestions for articles to be included in the final work).

No one was asked to keep precise statistics on how many authors were sought before an agreeable author was found. My sense is that the 2/e editors had a somewhat tougher time with this than the 1/e editors had (but on the other hand, the 2/e editors had all the 1/e authors to work with, which Smelser and Baltes certainly did not have). The 1/e editors report that about 60% of those invited to write articles agreed to do so on the first 'ask' (with equivalent success rates in each subsequent 'ask'). In 2/e (or so I would guess), the success rate was probably closer to 50% and possibly even lower. They also report that something in excess of 90% of those who agreed to write for 1/e in fact contributed "acceptable entries in time to be included…" In the 2/e case, we found ourselves still soliciting authors within a few weeks of the submission deadline and some dozens of authors pulled out of the project at the last minute. Still, when all the dust settled, there were just about 800 articles planned for both editions that never materialized and both editions ended up with just fewer than 4000 articles. Perhaps these are 'natural limits' for a work of this sort.

Biographies*

In the Introduction to 1/e, Smelser and Baltes provided a short history of and rationale for the decision to include a limited number of biographical articles (150 of them, to be exact). This was evidently a controversial and contested decision since some of those associated with 1/e felt that biographical articles had no place in an encyclopedia focused on substantive knowledge (versus the personalities of those who produced it). As Newton said (paraphrasing a passage from Bernard of Chartres), "If I have seen further, it is by standing on the shoulders of giants" (a passage made famous among social scientists by Robert K. Merton's *On the Shoulders of Giants* (1965)). In other words, discovery is only possible because its discoverer is able to refer to knowledge already gathered and accumulated by his or her predecessors; and since all discoveries – small and large, substantial and minor – contribute to the production and accumulation of knowledge, singling out particular scholars for special attention would be both pointless and invidious.

This position, although understandable, was abandoned in the first edition and remains so in the second, largely because it is not possible to understand the social sciences without knowing the individuals who contributed to it. C. Wright Mills once defined the sociological imagination as the intersection of biography and history (Mills, 1959). To know the social sciences therefore requires biographical and historical knowledge. The social sciences are distinguished from the physical and biological sciences in the way they produce knowledge because individual human beings, including social scientists, invest meaning in their actions. Only through understanding the meaning that individuals give to their actions are social scientists able to provide explanations of human behavior and its outcomes. And what applies to social action in general applies to the production of social science knowledge as well. It thus makes sense to include biographical accounts of social science personages who have been particularly distinguished in making sense of human action and have in turn made major contributions to social science knowledge. To acknowledge individual social scientists with biographical articles is also to acknowledge their special and particular insights.

Once the decision was made to include biographies in 1/e, the next major decision was whom to include and whom to leave out. Two arbitrary but defensible principles governed these decisions: (1) the total number of biographies was not to exceed 150 (chosen because it seemed like a manageable number) and (2) only biographies of the dead would be included. The 1/e section editor for biographies, Karl Ulrich Mayer, consulted handbooks and encyclopedias, asked other section editors to name and rank the most important names in their respective disciplines, ran citation checks, and finally submitted a consolidated list to various experts for review. This resulted in some additions and some deletions and in the end 147 biographies made it into the first edition.

Instructions to authors writing these biographies directed them to include "a brief sketch of the major dates and events in the life of the biographee," to describe "the major contours of the [person's] substantive contribution," and to highlight the "importance and relevance of the biographee's work for the social and behavioral sciences." Largely the same instructions were given to 2/e biographers.

The selection criteria for 2/e were very different. First, on the reasoning that well-done biographies of leading figures is one of the things that draw readers to a work such as this, the total number of biographies was

* My thanks to Andreas Hess for drafting this section of the Introduction.

increased by more than 100 (to just over 250). In a major departure from 1/e, much of the increase is made up of biographies of the living. The 1/e restriction that excluded living persons resulted in anomalies that we thought needed to be addressed. As life expectancy has expanded in the twentieth and twenty-first centuries, so have the life spans of social scientists. Claude Levi-Strauss, to cite one obvious example, lived to the age of 101 years. When 1/e was published, he was in his 90s, was widely cited, was recognized universally as a modern classic, indeed a genius, of social anthropology – and yet, owing simply to his longevity, he was not included in the 1/e biographies. Biographies of, for example, the economist Herbert Simon, the political economist Albert O. Hirschman, the sociologist and philosopher Jürgen Habermas, and the linguist Noam Chomsky were all excluded for the same reason; indeed, Habermas and Chomsky still live as this is being written (Fall, 2014). In all these cases, the major works had been produced decades earlier, their major imprints on the social and behavioral sciences were already evident, their eventual inclusion in works such as this was inevitable. Are readers to be deprived of accounts of their lives, times, and contributions just because they have survived into deep old age?

Once the decision was made to include biographies of the living, however, it was not always easy to decide who among the living merited inclusion. Often the editors had to make decisions on a case-by-case basis, frequently in extended consultation with colleagues or experts in the field. Criteria used to make these decisions were whether the potential biographee had a reputation beyond one culture, nation, or language group; whether there was a record of sustained production over several decades; and whether there was an impact beyond the confines of a single discipline. These criteria reduced our list of suggested biographees considerably. Early lists of candidates numbered as many as 200 new names (in addition to the 147 biographies included in 1/e). In the end, as noted earlier, somewhat more than 100 new names were added.

In a few cases, persons were included that arguably did not satisfy our inclusion criteria. One such is Raul Hilberg, who became famous mainly for having written one very important book, *The Destruction of the European Jews* (1961). Hilberg's book is still regarded as the seminal work in Holocaust studies, a field of research that came to prominence much later; we felt that his signal contributions to Holocaust studies merited a biographical article. Much the same could be said, perhaps, of André Gorz, a well-known social theorist from France, and Albert Memmi, whose work is on colonialism, anticolonialism, and racism. These and other examples could and probably will raise questions about the porousness of our criteria. Whether we were right in giving 'trespassers' their space is open to debate. In any case, whether Hilberg, Gorz, Memmi, and others do or do not merit their biographies is for readers, not us, to decide.

Other important changes in the 2/e biographies section include, first, a conscious effort to attain a better gender balance, including more women both as biographees and as authors; and second, expanding the biographies both geographically and culturally. In the end we made some inroads in both respects but fell short of our internal goals. One of the main reasons for this is that any encyclopedia must, in the first instance, be true to the disciplines it represents. This means being true to the real status of important players, their networks and disciplinary power relations, and their academic capital in their respective fields and beyond. Change in these respects has been noticeable; certainly, the growth of the social sciences in Asia has been remarkable; and in most disciplines, the proportional presence of women has increased. But modest change in the right direction does not a revolution make. Too many nonwhite, non-Western, and nonmale practitioners are still being left out on the disciplinary peripheries and are not fully represented – not in their home disciplines and not in our encyclopedia either.

We state this fact with regret. In many cases, the limiting factor is not excellence but simple visibility. Being part of the trans-Atlantic social science dialogue and engaging this dialog mainly in English translates into more visibility, as discussed earlier. This gets a scholar on the radar screen. Equally excellent work engaging other intellectual dialogues in languages other than English does not. A great many outstanding scholars have thus gone unrecognized in 2/e for precisely this reason. That being said, strenuous efforts were made to make the 2/e biographies more inclusive. Among those included are the Argentinean educationalist Sarmiento, the Brazilian sociologist Cardoso, and the Japanese political scientist Maruyama, to name just a few. This is, however, 'just a few' of the many dozens of prominent social and behavioral scientists 'out there' whom we would have included had we been given more time and more resources (to get non-English works translated, for example). We do feel that we have made some important inroads and beg the reader's understanding of the limits within which we worked. We can only hope that the next edition will strive for more inclusiveness and better representation than we were able to achieve.

Another entirely new feature in the 2/e biographies is the series of 'collective biographies.' In many instances, the intellectual lives of individuals who work in research groups intersect and form a network that makes the

entire group (or paradigm) successful. Examples include articles on the Durkheimians, the Annales School, the Frankfurt School, and several others.

As indicated earlier, instructions to authors were changed little from 1/e. All authors were asked (1) to include the most important biographical facts (country of origin, generation, education, influences, other formative experiences, networks, etc.); (2) to list the most important output (discoveries, publications, etc.) and to briefly discuss the subject matter and content of the most important publications or discoveries; (3) to look at the lasting impact of the person and his or her work (if possible, beyond just one discipline, language group, or culture); and (4) to provide a bibliography of primary and secondary sources related to the biographee and his or her work. Most authors stuck to these guidelines.

Finally, we state for the record that there are a number of important social and behavioral scientists that we would have liked to include but for whom we were unable to find a proper biographer. The search for biographers went on for nearly 4 years. In many cases, our first-choice author agreed at once, but in other cases, we approached four, five, or even more people before an agreeable author was found. And in about two dozen cases, no such author was ever found, with the result that a deserving person's biography had to be dropped. Forgoing a case-by-case discussion of these deletions, let it be simply noted that this is why we have not included biographies of people such as Amartya Sen, the economist and social philosopher; Raymond Boudon, the French sociologist; Ronald Dworkin, the legal theorist; Avishai Margalit, the philosopher; or a collective article for the British Marxist historians (Eric Hobsbawm, E.P. Thompson, Christopher Hill, and Perry Anderson). Perhaps our most regrettable omission is Neil Smelser himself, for whom no biographer could be found despite at least a dozen attempts. (Paul Baltes's biography is included.) Neil is one of the giants on whose shoulders we all stand.

Redundancy

I mentioned earlier that in the beginning of the project, there was no 'map' linking each of the 1/e articles to its respective 1/e Section. Our efforts to create such a map invariably bogged down every time we hit an article that could plausibly belong to any of several sections, which was often. Obviously, it would have been possible to force every article into a 2/e section, but at the time it seemed advisable to involve the editors themselves in these decisions. So on numerous occasions, I distributed lists of 'orphaned' articles (articles for which no home had yet been designated) to the area and section editors, asking for foster parents to volunteer. Eventually, of course, every article found a home, but at a relatively late date in the process, I became aware that a few dozen articles had found more than one home. That is, some of the editors adopted articles without filing the appropriate paperwork with the editor in chief! In such cases, the result was two articles on the 'same' topic. (The 2/e Table of Contents was scoured multiple times looking for precisely these kinds of duplications but in the end, several proved elusive.)

In the large majority of cases, the content of the 'duplicate' articles was sufficiently distinct that both articles were retained, often with some retitling to help readers differentiate between them. For example, readers will find two articles on 'social identity.' One was recruited for the section on social psychology; the other for the sociology section. With rare exception, the two articles discuss different aspects of social identity from entirely different disciplinary angles; indeed, the two articles share only a small handful of common references. So it was an easy decision to retain them both: one appears here as Social Identity in Social Psychology; the other as Social Identity in Sociology. Careful readers will find perhaps a score of similar cases in the encyclopedia.

Alas, in a few regrettable cases, the overlap between duplicate articles was so pronounced that one of the articles had to be deleted. Since by the time these problems surfaced the articles had (often) been written and rewritten several times and had been accepted by both the section and area editors, the last-minute decision to delete a redundant article was painful. My sincere apologies to the authors involved.

Some redundancy in a work of this scope and aspiration is not only inevitable, it is probably also desirable. A reader interested in, say, social inequality will (one hopes) want to know what the sociologists, anthropologists, economists, and geographers all have to say about that topic. And if a few of the many articles on the topic say more or less the same thing, then what harm is done? Editors at all levels were asked to be alert to redundancies across articles and the editorial record shows that many were. That being said, quite a bit of topical redundancy no doubt remains, and that is not (in general) a matter of concern. It is what Smelser and Baltes refer to as the "inevitable residue of overlapping."

The Review Process

Once the table of contents had stabilized, each of the editors was asked to review the 1/e articles assigned to their section or area and come to various decisions. In some cases, 1/e articles could be reprinted more or less 'as is,' with perhaps some updating of references for readers seeking entry points into the current literature. This was especially the case with what were eventually designated as 'legacy articles,' e.g., Gabriel Almond's article on Civic Culture, James Gregor's article on Dictatorship, &c. In other cases, the 1/e articles needed some updating to be suitable for 2/e, either by their original authors when available or by others recruited specifically for the purpose. The general rule was that all 1/e authors would be offered the opportunity to do the updates themselves, and that other authors would be sought in the event of the original authors' declinations. In still other cases, the 1/e article was so obsolete than an entirely new article would be required. And then finally, the review of 1/e articles often revealed areas of current research that were inadequately covered; in these cases too, completely new articles would be sought.

Where appropriate, the relationship between the 1/e and 2/e versions of an article is spelled out in the article tagline. In many cases, there were issues of authorship to resolve — a 1/e article written by *X* and completely revised by *Y* is *Y*'s article although *X* might be identified in the tagline; but what of an article written by *X*, now deceased, and only modestly revised and updated by *Y*? Every decision rule that I formulated to resolve such issues soon confronted an exceptional case where the rule did not seem to apply. So in the end, the only workable rule was that everyone should get proper credit for their intellectual property, whether prime author or reviser, whether living or dead. If exceptions to this rule have crept into the final product (as they almost certainly have), I offer my apologies to those whose work has been slighted or improperly recognized. Deciding on proper authorship for many of our articles was a far more involved and difficult task than expected.

The section editors formed the first line of editorial defense and were the ones to whom article drafts were originally submitted. The section editors read and commented upon the draft articles and returned them to authors for revision. It is a rare article that appears here in its original form: on average, articles were revised two or three times before being sent to the area editors and subsequently on to me; in many cases, it was more like five or six revisions, with subsequent revisions at the request of the area editors and the editor in chief. And in some cases, articles were submitted to outside readers for independent review. As I stated earlier, the reviewing process was not blind, but it was quite thorough, as is reflected in the exceptional quality of the final product.

Internationalism and Inclusivity

A truly *International* Encyclopedia of the Social and Behavioral Sciences would of course require a global network of editors and authors *and* a commitment to internationalize the content of the work wherever possible. With respect to the editorial team for 2/e, this was definitely realized. The section editors and editors in chief who produced the first edition were drawn from only nine countries: The United States, Germany, Italy, Canada, Sweden, Australia, France, Switzerland, and the UK. Two-thirds of those editors were from the USA and only 13% were women. Area and section editors for 2/e represent 21 countries, US scholars make up only 38% of the total, and women comprise 36%. Thus, the proportional representation of women among the editors was nearly tripled in 2/e over 1/e while the predominance of the USA was halved. Nations represented among the editors of 2/e that were not represented in 1/e include Luxembourg, Greece, Finland, Japan, China, Ireland, Singapore, Spain, Russia, Austria, Israel, and the Netherlands. The presence of several Asian nations on this list is particularly gratifying. To be sure, the North Americans and Western Europeans still predominate, but they no longer monopolize the field.

Adding the International Board of Consulting Editors (see the following statement of Acknowledgments) increases the internationalism of the editorial team even further. Of the 45 members of that Board, only 12 (27%) are US social and behavioral scientists. Countries represented on that Board that are not otherwise part of the editorial team include three Central and South American nations (Venezuela, Argentina, Costa Rica), several Asian nations (the Philippines, Malaysia, South Korea, India), a few Western European nations (Norway, Denmark), two representatives from Central and Eastern Europe (Hungary, Croatia), two from the Middle East (Lebanon, Qatar), and one from South Africa. These editions bring to 35 the total number of countries with representation on the IESBS editorial team.

Much the same can be said of the 2/e authors, who are also more international than the 1/e authors had been. Smelser and Baltes noted in their Introduction that while authors from 51 nations were represented in the work,

58% of the authors were from North America and another 35% were from (mainly Western) Europe. "As to gender composition, 21% of the [1/e] authors were women." In 2/e, the proportion of women among the authors has increased slightly to approximately 25% and the percentage of North American authors has declined to fewer than half. Again, North America and Western Europe still contribute the larger share of the 2/e authors but the growing representation of social and behavioral science authors outside the West is both noteworthy and encouraging.

Another important point is that the international scope of the project is much more pronounced than editors' and authors' current affiliations would lead one to conclude. (This would have been equally true in 1/e as well.) Consider, for example, Michiru Nagatsu, author of our article 03053 on the history of behavioral economics. Dr Nagatsu was born in Japan and retains Japanese citizenship but was educated at Exeter and the London School of Economics and Political Science and wrote his IESBS 2/e article while on a postdoctoral fellowship in Finland. Or Guillermina Jasso, area editor for Area Three. Jasso was born in the USA, received her PhD from Johns Hopkins, and is on the faculty at New York University. By any standard, she would count as a US sociologist in our compilations. Yet her parents were Mexican of Basque, Spanish, Portuguese, and Dutch origins; Spanish is her native language; over the course of her distinguished career, she has published with coauthors from Germany, India, Israel, Mexico, the Netherlands, and Sweden; and she holds a permanent research fellowship at IZA, the Institute for the Study of Labor, in Bonn, Germany. Scoring her as 'USA' scarcely does justice to her biography or to the international perspective she brought to the editorial task.

What is true of author Nagatsu and editor Jasso is true in degrees of virtually the entire roster of IESBS participants. If one includes place of birth, citizenship, where educated, sites of research, visiting appointments, sites of fellowships, honorary professorships, invited lectures, and on through the list of highlights in a modern academic career, it is safe to say that every nook and cranny of the globe (save, possibly, Antarctica) is represented somewhere in the biographies of IESBS authors and editors. The true measure of internationalism, in short, is not so much where people come from or where they currently are, but rather the extent to which they bring a sensitivity and commitment to cultural and national differences into their work. Whether this was or was not realized in 2/e is for readers to decide.

Concluding Observations

Smelser and Baltes aspired in the first edition of this work to "assemble the whole range of knowledge – vast and complex as it is – of the social and behavioral sciences in one place." Since what does and does not qualify as 'social and behavioral science' is itself contested, it is not surprising that nearly every one of the market reviews commissioned by Elsevier to guide the development of the current edition noted content omissions in 1/e that reduced its usefulness and that needed to be addressed in a second edition. Critics can and no doubt will say the same about 2/e. I have already mentioned the nearly 800 articles that appeared on the 2/e Table of Contents at one time or another but that will not be found in the final product, either because agreeable authors could not be located or (less often) because agreeable authors never produced an acceptable article. And it is pretty easy to identify whole chunks of present-day social and behavioral science that are given short shrift, or no shrift at all, in this work – not because these chunks were judged to be unimportant but because limits of time, space, resources, and networks meant that some elements of the contemporary social science enterprise never came to our attention.

The social and behavioral sciences begin with what artificial intelligence guru Marvin Minsky once described as a "three pound computer made out of meat" – the human brain, which for all we know is the most complicated three-pound hunk of matter in the universe – and end with a thoroughly globalized culture and social structure that encompasses all aspects of our species' physical, biological, psychological, social, emotional, cultural, and spiritual lives. We are the most successful species ever to have inhabited the planet; we have colonized every inhabitable piece of dirt; our range extends everywhere; all the earth's resources lay at our command. To record all that has come to be known about human origins, evolution, language, culture, and social structure – everything we know about human emotions, identity, love, religion, family, economics, politics, domination, exploitation, and on through a very long list – would require orders of magnitude more volumes than the mere 26 volumes that comprise the present work.

We have come increasingly to the realization that what is social and human about our species is very intimately connected to our biological, genetic, and evolutionary inheritance. At the same time, the brain specifically and biological evolution more generally "cannot be viewed separately from the material, historical and

social circumstances that produce it" (Berntsen and Baker, 2015). As these authors put it, biology and culture are 'mutually constitutive.' Fifteen years ago, the editors of the first edition remarked on "ferment at the boundaries between the biological and the behavioral and social sciences." And while there are still important controversies, much of the ferment has yielded to cooperation as we are just now beginning to explore this endlessly complex web of interconnectedness between our biological and social selves. It is an easy and nearly inevitable conclusion, thus, that the third edition of the IESBS will contain a great deal more of the work being done at this intersection than 2/e was able to accommodate.

To conclude on a purely personal note, the 5 years I have spent working on this project produced many professional and personal gratifications, none quite so delicious as the certain knowledge that I would learn something new every single day. My work on 2/e exposed me to literature I never knew existed and to aspects of the social and behavioral sciences of which I was at best dimly aware. I can only hope that readers who come to these pages will find them as enriching as I have.

ACKNOWLEDGMENTS

A work of this scale is inevitably a communal enterprise involving many hundreds of editors, authors, reviewers, technical support people, colleagues, professional acquaintances, and friends who have provided input, advice, encouragement, and assistance over the past five years. Any listing is bound to be incomplete, so my apologies in advance to those who expected to be mentioned here but are not. Be assured that the slight is not intentional.

My negotiations with Elsevier about this project began early in 2010. By May of that year, I had committed to the project and have been working on it at varying levels of intensity ever since — often on weekends, during holidays, and whenever else I could snatch a useable chunk of time. So my first acknowledgment must be to my wife Chris for suffering through my five year obsession, always with understanding and affection, usually with good cheer. Chris is probably the only person in the world who is happier than I am that the project is now completed.

I must also acknowledge an enormous intellectual debt to the editors in chief of the first edition of the *International Encyclopedia of the Social and Behavioral Sciences*, Drs Neil Smelser and Paul Baltes (the latter now deceased). Dr Smelser was gracious enough to serve as Chair Emeritus of the project's International Board of Consulting Editors and to put himself at my disposal as, in his words, "a battle-scarred veteran." The basic intellectual structure of this work is adopted more or less wholesale from the Smelser—Baltes edition, with a few exceptions noted earlier in the *Introduction*. Without the original to serve as the starting point and blueprint, it is hard to imagine even embarking on such a task, much less bringing it to completion. Their edition was hailed as "the largest corpus of knowledge about the social and behavioral sciences in existence," which is to say that it formed an *extremely* solid foundation from which to build the work you now hold in your hands.

The first edition was organized into 39 sections overseen by a team of 53 section editors. The structure of the second edition is slightly different. It is divided up into 10 broad 'Areas,' each with an Area Editor overseeing the work of between four and eight Section Editors. In all, the second edition is thus comprised of the 10 Areas subdivided into 53 Sections; the 53 Sections were developed by a team of 76 Section Editors. So whereas Smelser and Baltes had 53 colleagues to help complete the work, I had 84 (two of the Area Editors also edited their own sections). On pages i-v in the front matter to this work one finds an Editorial Board list showing the Area Editors, Section Editors, Sections, names, and affiliations of the entire editorial team — a team whose dedication and effort in behalf of the project has vastly exceeded the rate of pay. A more helpful, productive, or delightful group of scholarly collaborators is difficult to imagine.

What readers see in the listed Editorial Structure of the work is the *final* editorial team as it existed when the work went into production. As would be expected in a project of this duration, there was considerable turnover within the team as the project developed and as death, competing demands, and general indifference all took their toll. I am grateful, nonetheless, to everyone who agreed, at least initially, to participate in the project, whether or not they were able to stay involved to the very end.

Susan Hanson (Geography) and Ulf Hannerz (Anthropology) are owed a special note of thanks because, of the 53 Section Editors involved in the first edition, these are the only two who agreed to reprise their roles in the second. (Both also wisely requested and received coeditors to carry part of the load.) Persuading people to serve who had no real idea what they were getting into was challenge enough, but these two suffered through 1/e and were willing to do it all over again for 2/e. And for that, I am especially grateful.

Many of the editors benefitted from the assistance of colleagues and graduate students at their various institutions. There was no mechanism built into the editorial process to keep systematic track of this

assistance and so the listing below is certain to be incomplete. But I can at least acknowledge those of whom I am aware who contributed time and intellectual energy to the effort: Liam Morton and Andrea Livingstone (Psychiatry); Jennifer O'Connor and Alana Dorris (Applied, Industrial and Organizational Psychology); Jen Hanis-Martin (Sexuality); David Budde, Annette Stimmer, Nikolas Ott, and Franziska Pfeifer (Institutions and Infrastructure of Social and Behavioral Sciences); Matthew LeDuc and Scott Freeman (Contemporary Cultural Concerns); and Simone Dudziak (Public Policy). To those named, my thanks. To those omitted, my apologies.

A special note of thanks to Dr Donald J. Barrett. Don was originally recruited to develop an entirely new section of the second edition on Gay, Lesbian, Bisexual, and Transsexual Studies, completed the section in short order, then e-mailed me to ask if there was anything further he could do to be helpful. Consequently, he took a major hand in developing the section on Biographies and was quite helpful with many other sections too. He appears in the Editorial Structure both as a Section Editor and as a Senior Editorial Associate to acknowledge his yeoman service to the entire enterprise. Also listed as a Senior Editorial Associate is my colleague Dr Amy M. Donley, who has been with the project since the very beginning and who, more than once, was all that stood between me and madness. I am proud to count them both as colleagues, collaborators, and friends.

I am also pleased to acknowledge Don Barrett, Andreas Hess, Harry Whitaker, John Berry, Barbara Miller, Scott Bentley, and Claire Byrne for their incisive and helpful commentary on previous drafts of the Acknowledgments and Editor's Introduction.

The project's International Board of Consulting Editors, chaired by Smelser and Dr Peter Marsden of Harvard University, was formed late in 2011 as a 'sounding board' to be used by the Area and Section Editors in searching for topics and authors and to help push for greater internationalism in our coverage. As it turned out, several members of this Board also stepped up to write entries in their areas of expertise. The composition of this Board and the affiliations of the consulting editors (as they were when the Board was first formed, not necessarily as they are today) are as follows: Neil J. Smelser, *University of California, USA*; Peter V. Marsden, *Harvard University, USA*; Ronald F. Abler, *International Geographical Union, USA*; John Bacon-Shone, *University of Hong Kong, China*; Roberto Briceño-León, *Universidad Central de Venezuela, Venezuela*; Roel Bosker, *Rijksuniversiteit Groningen, The Netherlands*; Michael Burawoy, *University of California, Berkeley, USA*; Nestor T. Castro, *University of the Philippines, Philippines*; Dalton Conley, *New York University, USA*; Freek Cronjé, *North West University, South Africa*; Scott Davies, *McMaster University, Canada*; Abdul Rahman Haji Embong, *Malaysian Social Science Association, Malaysia*; Joan-Maria Esteban, *Barcelona Graduate School of Economics, Spain*; Robert S. Feldman, *University of Massachusetts, USA*; Sari Hanafi, *American University of Beirut, Lebanon*; Gudmund Hernes, *Norwegian Business School, Norway*; Sheila Jasanoff, *Harvard University, USA*; Tim Jensen, *University of Southern Denmark, Denmark*; Colin Jones, *University of London, UK*; Nadezhda Lebedeva, *Higher School of Economics; and National Research University, Russia*; Miklós Lévay, *Eötvös Lorand University, Hungary*; Dinka Marinovic Jerolimov, *Institute for Social Research, Croatia*; Laurie M. Joyner, *Rollins College, USA*; Ferenc Kiefer, *Hungarian Academy of Sciences, Hungary*; Pan Suk Kim, *Yonsei University, South Korea*; Katsuya Kodama, *International Peace Research Association; and Mie University, Japan*; Allan Lavell, *Facultad Latinoamericana de Ciencias Sociales (FLACSO), Costa Rica*; Jake Lynch, *University of Sydney, Australia*; Cecilia Mabragana, *Consejo Nacional de Investigaciones Cientificas y Tecnicas (CONICET), Argentina*; William McBride, *Purdue University, USA*; Ishwar Modi, *University of Rajasthan, India*; Leonardo Morlino, *School of Government, Italy*; Melvin L. Oliver, *University of California, USA*; Angela M. O'Rand, *Duke University, USA*; Kenneth Prewitt, *Columbia University, USA*; Thilo Rehren, *University College London Qatar, Qatar*; Colette Sabatier, *Université Victor Segalen, France*; Philip Schofield, *University College, UK*; Rainer K. Silbereisen, *University of Jena, Germany*; Chamhuri bin Siwar, *National University of Malaysia, Malaysia*; Tom W. Smith, *World Association for Public Opinion Research, USA*; Catalina Smulovitz, *Universidad Torcuato Di Tella Miñones, Argentina*; Philip Spinhoven, *Leiden University, The Netherlands*; Sukhadeo Thorat, *Indian Council of Social Science Research, India*; Nigel Thrift, *University of Warwick, UK*; John R. Townshend, *University of Maryland, USA*; Gisèle Yasmeen, *Social Sciences and Humanities Research Council of Canada, Canada*.

Searching for an editorial team to represent every social science discipline and every region of the globe quickly exposed the deficiencies in my personal network, so I am indebted to a very large number of scholars around the world for calling names of prospects to my attention, allowing me to drop their names in the recruitment effort, or otherwise helping me find people with the expertise and commitment required for the job. In most cases, this is a list of people who were invited onto the editorial team in some capacity,

demurred, but made valuable suggestions about others to contact. In several cases, people are listed because they engaged me in intellectual discussions about the structure, format, and even advisability of this work, or simply replied to a cold-call e-mail in pleasant, kind, helpful, or informative ways. Again ignoring the risk of omission, my sincere personal thanks to those named below for their contributions large and small to the final product:

Doug Anderton, Juri Allik, George Armelagos, Susan Ayers, Amanda Baumle, Janeen Baxter, Jess ben-Habib, Joao Biehl, David Blanchflower, Hans-Peter Blossfeld, Jason Boardman, Dorret Boomsma, Roel Bosker, Henry Brady, Martin Bulmer, Craig Calhoun, Miguel Centeno, William Cockerham, Mark Nathan Cohen, Amelie Constant, Simon Cottle, Connie Citro, Eileen Crimmons, James Curran, Scott Davies, Donatella Della Porta, George Downs, Francis Dodoo, David Dozois, Sonja Drobnick, Jaap Dronkers, John Dryzek, Riley Dunlap, Lauren Edelman, David Elesh, Paula England, Nancy Eisenberg, Geoffrey Evans, Miriam Faust, Robert Feenstra, Marcus Feldman, Stanley Feldman, Ronald Fischer, James Fowler, Jeremy Freese, Angela D. Friederici, Michael Frumpkin, Masahisa Fujita, Nicole M. Gage, Nancy Gallini, Rosemary Gartner, Morton Ann Gernsbacher, Robert Goodin, John Grattan, Lance Gravlee, David Greenberg, Wendy Griswold, Melanie Guldi, Monica Das Gupta, Peter Hatemi, Robert Haveman, Karen Heimer, John Hibbing, Sarah Blaffer Hrdy, Sheila Jasanoff, Kelly Kadera, Cigdem Kagitcibasi, David Kavanaugh, Roger Keil, Byungkook Kim, Rob Kitchin, Jack Knight, Lyle Konigsberg, Candace Kruttschnitt, Helen Ladd, Phillip Lane, Graeme Lang, Janet Lauritsen, Ashley Leeds, Evelyn Lehrer, Richard Lerner, David Lewis, Tim Liao, Tom Linneman, Norman Long, Karen Lyons, Ruth Mace, Gary Marks, Herbert Marsh, Karl-Ulrich Mayer, Lorraine Mazerolle, Rose McDermott, Susan Michie, Harry Minas, Peter Miller, S. Phillip Morgan, Victor Nee, Vin-Kim Nguyen, Paul Nieuwbeerta, Helga Nowotny, Howard Nusbaum, Claus Offe, Thomas Ollendick, Joan Orme, Dennis O'Rourke, Michael Overington, Catherine Panter-Brick, Susan Parnell, Deborah M. Pearsall, Gerard Pfann, Jon Pierre, Mike Ping, Jennifer Platt, Ken Prewitt, Cathy Price, Jill Quadnagno, Charles Ragin, Thilo Rehren, Ben Rosamond, Bo Rothstein, Beth Rubin, Heinrich Sauer, Peer Scheepers, Ralf Schwarzer, Moshe Semyonov, Michael Shanahan, Sara Shostak, Alan Sica, Rainer K. Silbereisen, Beth Simmons, Catalina Smulovitz, Michael Sobel, Diane Stone, Jill Stephenson, Rafe Stolzenberg, Miron Straf, Richard Swedberg, Alan C. Swedlund, Sidney Tarrow, Jacques-Francoise Thisse, Stefan Timmermans, Florencia Torche, Erik Tsang, Judy Treas, Billie Turner, Cees van der Eijk, Paul van Lange, James Vaupel, Karin Wahl-Jorgensen, Mitchell G. Weiss, Neil Whitehead, Pamela Wilcox, Bjorn Wittrock, Cornelia Woll, Gisele Yasmeen, and Barbie Zelizer.

Gratitude is owed as well to the many colleagues at Elsevier who contributed to the production of this volume. My first debt is to Claire Byrne, the project's Content Project Manager and the head of the Major Reference Works (MRW) team that managed the day-to-day *Sturm und Drang* of the project: aggrieved, confused, or delinquent authors, missed deadlines, testy and intransigent editors, and the often-maddening work style of the Editor in Chief. I am sure there were days when Claire wanted to tear her hair out, but to external appearances, she was an island of calm in a sea of turmoil. She was also exceptionally good at her job.

Claire's MRW team comprised Richard Berryman, Will Bowden-Green, Esmond Collins, Mark Harper, Sam Mahfoudh, Mike Nicholls, Gemma Tomalin, Joanne Williams, and Marise Willis. No matter what issue or problem I faced, one of these fine, capable people was always available to step up with a solution, invariably offered in a spirit of cooperation and good cheer. They have been to IESBS 2/e what tech support is to the modern computerized office. Getting this work completed without their help is inconceivable.

Thanks also to the succession of Elsevier's Acquisitions Editors who managed the finances and internal politics of the project: to Scott Bentley, whose gentle suasions pulled me into the project in the beginning; to Karen Maloney and Peter Labella who ran the show in the middle period; and to Lisa Tickner who was in charge at the very end. These are the people on the front line in the endless war between the publisher, who wants things done now and at minimal expense, and the Editor in Chief, who was always asking for more time and more money. The many dozens of amicable compromises necessary to bring the project to completion were all ably negotiated by Scott, Karen, Peter, and Lisa, and for that, I am grateful indeed.

The University of Central Florida and its Department of Sociology have provided a congenial home for the project. My thanks in particular to Dean Michael Johnson; to the current and former chairs of my department, Jana L. Jasinski and Libby Mustaine; to my faculty colleagues Liz Grauerholz, Phillip 'Hutch' Pollock, Bruce Wilson, Melanie Guldi, Stacy Barber, Tosha Dupras, and John Schultz; and to current and former graduate students Thomas Hall, Sara Strickhouser, Betsy Swart, Jordana Navarro, Marie Gualtieri, Shannon Simone, and Shannon Frey.

And most of all, my sincere thanks to the many thousands of authors whose work this is. When comparing the quality of the work contained within these pages to the authors' honoraria, it is obvious that IESBS 2/e is an act of collective charity by our authors to the disciplines they represent. It is my pleasure to thank our authors on behalf of the global social science community.

GUIDE TO USING THE ENCYCLOPEDIA

Structure of the Encyclopedia

The material in the Encyclopedia is arranged as a series of articles in alphabetical order.

There are four features to help you easily find the topic you are interested in an alphabetical contents list, cross-references to other relevant articles within each article, subject classification index, and a full subject index.

1. Alphabetical Contents List

The alphabetical contents list, which appears at the front of each volume, lists the articles in the order that they appear in that volume of the Encyclopedia. It includes both the volume number and the page number of each article.

2. Cross-references

All of the articles in the Encyclopedia have been cross-referenced. The cross-references, which appear at the end of an article as a See also list, serve three different functions:

a. To draw the reader's attention to related materials in other articles.
b. To indicate material that broadens and extends the scope of the article.
c. To indicate material that covers a topic in more depth.

3. Subject Classification Index

This index appears in Volume 26 and groups articles under subject headings that reflect the broad themes of Social and Behavioral Sciences. This index is useful for making quick connections between articles and locating the relevant article for a topic that is covered in more than one article. Under some section headings, you will find subheadings, if it is appropriate for the articles in a subject area to be grouped into more specific subareas.

4. Contributors

At the start of each volume, there is list of the authors who contributed to that volume.

5. Index

The index appears in Volume 26. The index includes page numbers for quick reference to the information you are looking for. The index articles differentiate between references to whole article, a part of an article, and a table or figure.

Reading Nonalphabetic Scripts

Takeshi Hatta, Kansai University of Welfare Science and Nagoya University, Takatsuki City, Osaka, Japan

© 2015 Elsevier Ltd. All rights reserved.

This article is a revision of the previous edition article by T. Hatta, volume 19, pp. 12797–12800, © 2001, Elsevier Ltd.

Abstract

The unique characteristics of Japanese language such as Japanese sound system contains few sounds. Japanese vocabulary consists of four word types (Japanese origin, Sino-Japanese, foreign-loan word, and hybrids), and Japanese writing system consists of five kinds of script type (Kanji, Hirakana, Katakana, Roman alphabet, and Arabic numerals). Among five script types, Kanji (logographic symbol) and two types of Kana (phonetic symbol) are most frequently employed in writing Japanese. Cognitive psychological studies, which examined this uniqueness, are reviewed. Especially, cognitive psychological studies which investigated how people read the Japanese text written by five kinds of scripts and how people select one special script type in writing Japanese text are introduced. Findings of neuropsychological studies by brain-damaged people as well as brain-imaging studies by intact people, which examined if Kanji and Kana are processed differentially in reading also are reviewed.

Japanese Language

Linguistically, Japanese does not relate to Chinese, Korean, and English, though it is similar to Korean in syntax, but not in speech sounds and vocabulary. However, Japanese has borrowed many words and characters mainly from Chinese. Almost all indigenous people living in Japan speak Japanese, and ethnic Japanese living outside of Japan also do. There are about 130 million Japanese speakers, and Japanese ranks sixth among the languages of the world after Chinese, English, Russian, Hindi, and Spanish.

The Japanese language employs five vowels and 16 consonants. Compared with other languages such as English, the Japanese sound system contains many sounds. The Japanese sound system uses a unit called 'mora,' which is a short beat, the time to pronounce a short syllable. Mora is the main unit in Japanese language, and also the unit of the Japanese phonetic scripts, hirakana (or hiragana) and katakana. Each Japanese syllabary sign is based upon mora. There are 110 different moras or syllables in Japanese. It is one of the smallest inventories of any major languages. For example, 400 syllables in Chinese, and several thousand in English. The small inventory of Japanese sounds gives rise to many homophones but it is easy to be represented by a simple syllabary.

The Japanese vocabulary consists of four word types, Japanese origin (47.5%), Sino-Japanese (36.7%; long years ago adopted from China), foreign-loan word (9.8%; mostly European adopted in modern times), and hybrids (6.0%; Sino-Japanese or foreign word stems with Japanese endings).

Japanese Writing System

Japanese writing system consists of five kinds of script type, kanji, katakana, Roman alphabet, and Arabic numerals. Among these, the first three script types are employed most frequently in Japanese writings. Japanese text consists these five kinds of scripts, and it is also true that both the traditional vertical (tategaki) from top to bottom style and the yokogaki from left to right style are used depending on the type of written materials. For example, newspaper is printed in takegaki style whereas academic journals are printed in yokogaki style.

Kanji Script and Reading

As the results of waves of Chinese and Korean emigration to Japan during fourth and seventh centuries AD, Chinese-based culture mainly in the form of Confucian classics, medicine, and Buddhism came to Japan. A writing system with Chinese characters was, therefore, the only script until two forms of syllabary, hiragana and katakana, were created out of kanji during the nineth century AD. 'Kan-on' kanji readings were borrowings from Confucian scholarship. Chinese 'Hanzi,' associated with Han Dynasty period, became Japanese 'Kanji,' which remains the backbone of the Japanese writing system. As Japanese Kanji borrowed Hanzi in distinct historical periods, different pronunciations were adopted for these kanji and makes reading complicated in modern writing systems. The feature of having multiple readings for many kanji characters in Japanese is different from those of Chinese and Korean, which have only a single reading.

The Japanese language uses not only Chinese and native readings to the logographic characters, but also several varieties of each type of reading, which makes reading characters complicated. For example, Mandarin Chinese read the simple character for '10' 十 as one sound 'shi' and Korean read it 'sip' (no tone or soundless). Both Languages use only one reading; however Japanese speakers read the character, 'to,' 'toh,' 'so,' 'jyu,' 'jutt,' all without tone (Taylor and Taylor, 1995). The first three sounds are the example of Kun readings (Japanese native readings), while the others are 'On'-readings (Chinese readings). The Kun reading is quite different from the Chinese because the two languages are unrelated. Besides Kun reading, most Kanji have one or more on-readings which are not identical with Chinese sounds. Depending upon when and where the Chinese characters were borrowed, four different

types of on-reading (go-on, kan-on, toh-soh-on, and habitual one) were agreed. Most Japanese kanji are given only one of the four types of on-readings.

The number of Kanji is enormous. Kanji dictionaries contain between 12 000 and 50 000 entries. In 1981, the Japanese Ministry of Education attempted to restrict the number of kanji as 'joyo kanji' to be used in educational system. This contains 1945 Kanji but because almost kanji possess On- and Kun-readings, Japanese people therefore learn a total of 4084 kanji reading during their first 9 years of education. Generally, each kanji consists of the combination of radicals. There are 250 kinds of radicals, each consisting of between 1 and 17 strokes. Most radicals consist of two to nine strokes (Ueda et al., 1993). As the number of Kanji is so huge, this reduces any difficulties in understanding homophones. However, there is a clear asymmetry between reading and writing abilities and it is true that some adult Japanese fail to read even joyo Kanji.

Cognitive psychologists once suggested that the processing route of reading depended upon the type of orthography, that is, kanji has a single route from orthography to semantics, bypassing the contribution of phonological information, while kana travel a phonological route to access semantics. But this is too simple an explanation. Recent reviews of kanji studies suggest that it is reasonable to conclude that, depending upon the task settings, familiarity, frequency, and complexity of kanji, one of the most efficient processing routes of phonology-based or grapheme-based routes (or both routes) is employed access to semantics (Kess and Miyamoto, 1999). However, in the case of high-frequency and high-familiarity kanji, semantic access is achieved only through the grapheme-based route, and it is not specific to Japanese. There are examples in alphabetic system where the cognitive route is also direct from grapheme to semantics.

As shown in Table 1, complex Kanji consists of semantic and phonetic radicals, hen (left hand), tsukuri (right hand), kanmuri (top), ashi (bottom), kamae (enclosure), tare (top-left), and nyoo (left-bottom). Each acts differentially in reading. That is, generally, semantic radicals give clues to meanings whereas phonetic radicals give clues to pronunciation. Research findings also suggest that right-hand radical is more informative than the left.

Many words in Japanese are represented not only by individual kanji but also by a compound that is polysyllabic composite between two and four kanji usually carrying an on-reading. More than 50% words in most Japanese dictionaries are compound Kanji. Research findings also suggest that reading processes of kanji compound words constitute another groupings. In addition to the frequency of the compound word itself, first kanji in a compound is important, because the first kanji defines the range of possible collocations in the cohort of potential kanji compounds.

There is strong evidence that the individual kanji are processed as a recognition unit and kanji compounds themselves are also the recognition units. A case has been that one agraphic patient was able to read the single kanji 手 'hand' and 紙 'paper' but failed to read their coupling as 手紙 'letter,' while another patient had less difficulty in reading a compound word but could not read single kanji which constituted the compound word (Hatta et al., 1998). This double dissociation suggests that single and compound kanji words are stored with different addresses in mental lexicon.

Table 1 Samples of radicals

Radicals	*Examples*
Hen	波 (Wave) 河 (River)
Tsukuri	清 (Clear water) 晴 (Clear weather)
Kanmuri	草 (Grass) 花 (Flower)
Ashi	熊 (Bear) 馬 (Horse)
Kamae	国 (State) 囲 (To enclose)
Tare	庭 (Garden) 店 (Shop)
Nyo	返 (To return) 逃 (To escape)

Kana Scripts and Reading

In addition to kanji, there are two syllabary types of script in Japanese, hiragana and katakana (see Table 2). The kana unit represents a sound unit, which corresponds roughly to a syllable. Both scripts contain 46 basic symbols and 25 additional symbols with diacritic marks. Hiragana and katakana share the same syllabic reference point; therefore the same syllable can be written by either system. Hiragana is cursive in shape as shown in Table 2 and used mainly for some content words, morphological endings, function words, and the rest of the grammatical scaffoldings of sentences. In contrast, katakana is angular in shape and is used for writing foreign-loan words.

Kana gradually developed out of Chinese characters in the following order: kanji, kanji as phonetic signs, simplified kanji shapes, and kana. During this development, mainly female authors used hiragana to write letters, poems, diaries, and stories; this is because hiragana is a graceful cursive form of its original kanji. For a long time, it has been the convention that a cursively simplified hiragana is used for grammatical morphemes, and angular simplified katakana is used for foreign-loan words and onomatopoeia. However, an explanation for the use of both types of scripts because of different role in syntax cannot be the only reason why Japanese have kept three kinds of script usage irrespective of high cost. Japanese people might have found it useful or convenient to express semantic emotional information by employing different types of script.

Conventionally, there is a connection between orthography type and word used. This has a strong effect on Japanese word readings. Japanese people possess a strong semantic emotional image for each type of script such as kanji is hard, difficult, intellectual, vigorous, old, masculine, formal; hiragana is soft, round, tender, simple, childish, feminine, lovely; and katakana is angular, hard, cold, simple, new, sharp, exotic (Iwahara et al., 2003). In reading text, Japanese must activate different mental representations depending on types of scripts. That is, Japanese

Table 2 Hiragana, Katakana, and Kanji description of the word, firefly dream

Hiragana	ほたる	ゆめ
Katakana	ホタル	ユメ
Kanji	蛍	夢

may employ shallow (morphological) cues to generate mental representations from text.

Japanese people sometimes employ this emotional image of a script when writing, irrespective of the conventional usage of scripts and words. For example, reading experiments suggested that when Japanese see kanji word of chair 椅子, an image of an old fashioned strongly built chair is generated; when they see katakana word for chair イス, they imagine a modern and elegant chair; and in the case of hiragana for chair いす, they may imagine a simple wooden chair (Ukita et al., 1996). Writing experiments also indicated Japanese write text with due regard to the compatibility between mental representations and type of scripts (Iwahara et al., 2003).

Research Findings on Reading Studies in Cognitive and Neuropsychological Studies

The results of earlier cognitive psychological experiments suggest that orthographic configurations can be used to access directly phonological form, meaning, or both, depending on the processing task requirement. Although the role and the importance of these factors may differ for each orthography in respect to the processing strategy favored and the processing times required, Japanese seems not to be an exceptional writing system, but possesses idiosyncratic requirements of the world's writing systems.

However, neuropsychological studies have suggested that kanji and kana are processed differentially and stressed the importance of orthography difference in reading (Iwata, 1984; Yamadori, 1975). In alexia with agraphia due to angular gyrus lesions, kana reading is impaired more severely than kanji, whereas left posterior–inferior temporal lesions impair kanji reading (Iwata, 1984; Kawamura et al., 1987). These findings support the hypothesis that there are two pathways of reading in Japanese: one is the ventral pathway from the visual area in the occipital cortex via the posterior part of inferior and middle temporal gyli of the left hemisphere, which is used in semantic reading of kanji; the other is the dorsal route from the visual area via the angular gyrus to Wernicke's area, and is used for the phonological processing of kana reading.

Regarding the visual half field, several studies revealed that the right hemisphere contributes more than the left in kanji recognition. For example, a tendency toward a right hemisphere advantage was reported in the case of single kanji (Hatta, 1977), and in the case of two kanji nonword pairs (Sasanuma et al., 1977). On the other hand, a left hemisphere advantage was reported in the case of two kanji compound words (Hatta, 1978). Regarding to kana recognition, the left hemisphere contributes more than the right both in cases of single and word as well as in case of English (Hatta, 1978). By employing a new research method (MEG), Koyama et al. (1998) revealed that not only the left but also the right hemisphere is activated in reading kanji words and supports the view of the right hemisphere engagement in kanji reading. Same proposal was reported by the functional MRI method (Nakamura et al., 2005). These studies suggest the fact that hemisphere function in kanji reading is not the same as in the case of the reading of English and kana words.

Research Findings on Writing Studies in Cognitive and Neuropsychological Studies

Research findings for kanji and kana writing systems suggest a dissociation of kanji and kana processing by brain-damaged, brain-imaging, and behavioral research methods.

Just above Broca's area and anterior to the primary motor control area (Exner's area) damaged patients make kana word writing errors though they have not prominent difficulty in single kana writing. On the other hand, a left superior parietal lobule damage generates paragrahia, writing order error, and configuration distortion more in kanji than in kana writing, and a left occipito-temporal area B37 damage shows difficulty in kanji writing but no difficulty in kana writing (Otsuki, 2007). Left parietal and angular gyrus damage makes more errors in kana than in kanji writing, and left medial frontal area and thalamus damage invites difficulty in kanji and kana retrieve and paragraphia (Soma et al., 1989).

Brain imaging studies show a prominent activation in left occipito-temporal area B37 when participants retrieve kanji by semantic strategy (e.g., retrieve kanji that represents color) whereas Exner's area activates when they employ phonetic strategy, for example, retrieve kanji corresponding phoneme (Nakamura and Fukumura, 2007).

Behavioral studies showed that Japanese kanji writing errors consisted of largely three factors, phonological, semantic, and morphological, in spontaneous writing situation. Phonologically related errors are the most prominent, followed by orthographically related errors, and semantically related errors, including some overlap of these three types (Hatta et al., 1998).

Summary for Findings in Cognitive and Neuropsychological Studies

Kanji reading and writing relate to the networks including occipital and temporal lobes, whereas kana relate to the networks in frontal and parietal lobes including left inferior frontal gurus and motor association area (Iwata, 1986). Mechanism of Japanese reading and writing seems more complicate than alphabetic languages, which have only one type of scripts. Further studies concerning nonalphabetical scripts are necessary to answer the question that there is a language nonspecific universal cognitive processing in reading and writing.

Abstract

Reading acquisition is under the influence of the structure and function of the language itself, the individual's capacity to learn and the differential methods of instruction. Alphabetic languages vary from the bidirectionally consistent phoneme–grapheme–phoneme units of Finnish, to English as the most inconsistent for small units, but the latter of which increases in consistency as a function of increasing size of the unit (e.g., rime). Nonalphabetic Chinese places a heavy learning load through its inherently meaning-based logographic structure. Computer-assisted literacy training (e.g., GraphoGame) tailored to language features, teaching practices, and learner specific requirements can provide an adaptive and motivational learning experience.

Introduction

The acquisition of reading skill comprises several steps. The first step of reading is for the child to learn to connect the spoken language with the written language in order to sound and spell out the written language. For the majority, this step is mastered relatively well when formal reading instruction is begun. The next step involves the acquisition of sufficient fluency in reading in order to become fully literate and thus achieve the main goal of reading – that of comprehension. For the most part, this step can be achieved through simple exposure and practice.

There are many factors that affect reading acquisition; some internal, resulting from the readiness factors characteristic to the learner and others external, such as the nature of both the writing system and reading instruction. Below, we examine first the external factors and then those that are internal. In closing, we offer advice with regard to helping those children for whom reading acquisition is a challenge.

External Influences on Reading Acquisition

Reading Acquisition Is Affected by the Writing System

Learning to read starts with the acquisition of the central connections between language that is spoken (phonology) and language that is written (orthography). Such connection building can vary on two dimensions: in what is connected to writing – sounds or meaning – and what is the appropriate size of the to-be-learned unit in order to form a sufficiently reliable connection between spoken and written language. Independent of the writing system – either alphabetic (e.g., English or Finnish) or nonalphabetic (e.g., Chinese) – the typical beginnings to reading involve forming the connection between the spoken and written form.

Alphabetic writing systems range from consistent (or 'transparent' or 'shallow') to very inconsistent (or 'opaque' or 'deep') in terms of the relationship between the spoken and written unit. Alphabetic orthographies vary in their consistency at the level of the smallest functional spoken unit (i.e., the phoneme) and its relationship to its smallest counterpart in the written form – the corresponding letter(s) or grapheme. In nonalphabetic Chinese, writing does not reflect the segmental structure of speech and Chinese characters map to a whole morpheme (the smallest unit of meaning) syllable. Chinese children then have to learn thousands of lexical representations (Chinese characters) that include phonological, orthographical, and semantic (meaning) information.

Alphabetic Writing Systems

Transparent alphabetic writing systems can be so consistent that each phoneme is represented in writing by only one grapheme, independent of the context whereby only phonemic information is marked in the script. In more opaque orthographies, often morphological information is also coded – usually at the expense of phonemic regularity. As an example, in English the past tense ending of regular verbs is always written with '-ed', despite three possible pronunciations (/t/ in 'washed', /id/ in 'shouted', /d/ in 'roared'). Orthographic transparency is also related to historical changes in the development of a language. There is a general tendency that more recent orthographies, such as African local languages, are more transparent. Older orthographies – such as English – have often seen a number of spoken language-related changes that can cause written language to diverge from spoken. English is generally considered the most opaque of major alphabetic orthographies. This status is problematic since the majority of research knowledge regarding reading acquisition and acquisition-related problems stems from observations of readers of English.

Nonalphabetic Writing Systems

The Chinese orthography is often described as both logographic (visual symbols that represent words) and morphosyllabic. The basic unit of interface between the written word

and spoken language in Chinese is the morpheme. A character corresponds with one syllable and usually represents one morpheme. The most prominent characteristic of Chinese that differs from alphabetic languages lies in its complicated orthography and the relationships among visual symbol, speech sound, and semantic meaning. The Chinese writing system is also well known for its visual complexity. The units of orthographic structure in Chinese include strokes (丶, 丨, 丿), radicals (or root forms) (犭, 苗), or recurrent patterns of strokes and characters (猫, /mao1/, cat). The basic unit of Chinese, the character, is square shaped as opposed to the linear arrangement of English and other alphabetic scripts. Each character is a salient perceptual unit that differs from thousands of others in terms of individual strokes or the overall spatial configuration. About 72% of the characters that Chinese children learn during the 6 years of elementary school are compound and consist of radicals or components under the orthographic rules (Shu et al., 2003). There is some phonology information available in the semantic–phonetic compound characters (e.g., 烤, /kao3/, 'to burn'), which consist of a phonetic radical (考, /kao3/, exam) that provides cues to character pronunciation and a semantic radical (火, /huo3/, 'fire') that provides cues to character meaning. However, according to Shu et al.'s (2003) analysis, in all of the semantic–phonetic compound characters, about 29% are regular, in which these characters have exactly the same pronunciation as their phonetic radicals (e.g., 清/qing1/, with the phonetic, 青/qing1/) and about 40% are transparent, in which the radical provides reliable information about the meaning (e.g., 氵means 'water' and 清 means 'clear'). Chinese has a relatively simple syllable structure: a syllable consists of an onset and a rime and the lexical tone. The Chinese character directly maps onto morphemes rather than phonemes. Print-sound mapping in Chinese happens at the morpheme–syllable level, not at the grapheme–phoneme level as in English and other alphabetic scripts. There are approximately 7000 morphemes but only 1200 syllables in Mandarin. Thus, more than five morphemes, or characters, share one syllable. Homophones (same sounds but different meaning), e.g., syllable /yi4/ may correspond to 义 '*meaning*', or 易 '*easy*', 亿 '*a 100 million*', 宜 '*appropriate*', 益 '*benefit*', 艺 '*art*', 议 '*discuss*', and so on and homographs (same written form but different meaning), e.g., 草, may represent 'grass' in 草地 '*lawn*' or '*careless*' in 草率 '*cursory*', are very prevalent in Chinese, which weaken the differentiation of phonology. The connection from orthography to meaning is more systematic and efficient than that from orthography to phonology for Chinese character reading, while the situation is the opposite for English word reading (Yang et al., 2006).

Typical Acquisition of Reading and Writing

Alphabetic Writing Systems

In alphabetic writing systems, the majority of children can learn to read using phonics-based instruction. However, the more transparent the orthography, the faster the process of acquisition, as shown in **Figure 1**.

In contrast, the situation is completely different in nonalphabetic writing where the number of written language items (e.g., characters in Chinese) can be much larger than the number of letters in alphabetic writing (typically, not more than 30). To illustrate, the number of characters that require to be mastered by learners of Chinese over a number of years proceeds as shown in **Table 1**. The challenge faced by learners in these two different types of writing environment varies immensely; not least in terms of the amount of time required to acquire the basics of reading – from a very short time (i.e., a few months) for readers of fully transparent writing environments such as Finnish, to more than 6 years for readers of Chinese.

With speech typically considered as the 'primary' language (Mattingly, 1972), the child's awareness of speech sounds is viewed as implicit and consequently is not readily available for

Figure 1 Accuracy of word and pseudoword reading at the end of the first grade in 13 orthographies according to Seymour et al. (2003). Replicated from Handbook of Language Development, Blackwell (Lyytinen, H., Erskine, J., Tolvanen, A., et al., 2006. Trajectories of reading development: a follow-up from birth to school age of children with and without risk for dyslexia. Merrill-Palmer Quarterly 52 (3), 514–546).

Table 1 Number and proportion of characters by grade

Grade	*1*	*2*	*3*	*4*	*5*	*6*	*Total*
Number of characters	436	709	541	358	323	203	2570
Proportion of total	0.17	0.28	0.21	0.14	0.13	0.08	1.00

Table 1 is replicated from Shu, H., Chen, X., Anderson, R.C., et al., January/February 2003. Properties of school Chinese: implications for learning to read. Child Development 74 (1), 31.

intentional manipulation in the learner's mind. The shift to 'secondary' language, in the written form, requires the trigger that makes explicit the awareness of the constituent sounds that make up a given language (Gombert, 1992; Duncan et al., 1997). This transition can present as a challenge because, prior to formal instruction, children use spoken stimuli only to mediate meaningful messages to others and pay little heed to the individual sounds per se, except in language games. However, the step toward explicitly switching attention to the differentiation of small meaningless sound segments from each other is not large, especially when the child is assisted by a consistent alphabetic orthography (e.g., German, Spanish, Italian, Finnish, etc.). Within such contexts, in the reading direction, each letter or grapheme will, at most, cue only the smallest corresponding unit of the spoken language (phoneme). In the opposite direction that is spelling, each phoneme or sound unit will have a direct connection to a single letter when the consistency is high (with the exception of, e.g., German in this direction; see Landerl and Wimmer, 2008).

In the above-described alphabetic writing environments, the greatest challenge posed to the early reader relates to the perceptual differentiation of the sound units that she or he must learn in order to connect these to their corresponding letter(s). In the typical learner, such connections can be instructed effectively by drilling the connections (e.g., presenting a spoken phoneme and asking the child to choose the representative letter). For most children, the acquisition of the names of letters will make them sufficiently aware of phonemes to be able to piece together the constituent sounds in order to produce a pronounceable word sequence and without further reinforcement from intended meaning of the word. This claim is supported by the fact that a substantial number of Finnish children have managed to acquire the basics of grapheme–phoneme connections – the basis of reading – in their fully transparent orthography, prior to any formal instruction beginning at the age seven.

It is important to note that the level of consistent correspondence between spoken and written units of the languages varies along a continuum of 'orthographic depth' from shallow (e.g., Finnish) to deep (e.g., English, where transparency is minimal). The more transparent the orthography on the letter-sound level, the lesser is the learning burden and consequently, the easier it is to learn to sound out the letter sequences.

The development of reading therefore depends on differences in orthographic depth. Cross-language research has shown that learning to read an irregular orthography is harder and takes longer than learning to read a regular orthography (e.g., Frith et al., 1998; Goswami et al., 2001). Seymour et al. (2003) compared reading acquisition in 13 European countries and showed that average reading accuracy in most transparent orthographies reached ceiling at the end of grade 1, but only 34% in English. English-speaking children were estimated to need 2 or more years of experience to achieve the accuracy and fluency levels of the children in shallow orthographies, such as Finnish, on word identification.

Nonalphabetic Writing Systems

Although the mapping in Chinese from spelling to sound is syllable based, numerous studies of Chinese children's reading development have demonstrated that phonological skills, including syllable awareness, onset awareness, and rime awareness, are associated with Chinese character recognition (e.g., Chow et al., 2005; Siok and Fletcher, 2001). Lexical tone is a fundamental feature of Chinese spoken language in which four tones are used to distinguish meanings that are not differentiated by segmental information. Different levels of phonological awareness in Chinese emerge as the result of age or experience (Shu et al., 2008). Recent studies have also suggested Rapid Automatized Naming (RAN) to be a consistent predictor of Chinese reading development, in which linking printed information with a given phonological representation arbitrarily is important. RAN predicts reading development among Chinese children (Ho and Lai, 1999; Lei et al., 2011; Pan et al., 2011).

The acquisition of reading skill in Chinese requires learning to connect not only sounds, as is the beginning phase of Pinyin (Pinyin is a phonological coding system that represents Chinese characters using Roman alphabetic letters and lexical tone transcriptions. It represents single phonemes as in alphabetic scripts, but it is taught in a syllabic way, divided into onset, rime, and four lexical tones, e.g., the character 青 is transcribed as /qing1/ in Pinyin, where /q/ is the onset, /-ing/ is the rime, and /1/ is the lexical tone representing the pitch of speech.), but also meanings to the written symbols. In comparison to alphabetic languages, Chinese presents a huge challenge to learning to read. The Chinese learner must spend more than 5 years in learning more than 3000 simplified Chinese characters before they are equipped to read a newspaper. However, compared to learning to read English, learning to read Chinese is much more of a challenge. Learning to read Chinese depends on memory and integration of information about orthography, phonology, and semantics of thousands of characters in the early stages of reading. Thus, school children learning to read Chinese require a longer period in reading acquisition. Consequently, Chinese developmental dyslexia is usually diagnosed after forth grade when their classmates have learned to read (e.g., Shu et al., 2006).

We have partially unlocked the secrets of reading skill above in that the learner must first acquire the connections between the spoken and written units. The learning load varies from light (in transparent Finnish) to heavy (in nontransparent English), to cumbersome characters (in logographic Chinese). The fewer than 30 connections of transparent orthographies contrasts with the greater burden of learning the hundreds of potential correspondences in English, many of which can thwart pronunciation until all the letters are on view (e.g., 'thought'). In turn, the concept of transparency takes a back seat

in comparison to the learning load that is placed on the shoulders of the young reader of Chinese.

Larger, syllable- or word-level units that prevent a transparent match between the smaller constituent spoken and written units can place a significant load on memory as the current conventional route to their learning is through repetition or rote learning as each must be learned almost individually. Such a writing system could be highly detrimental in the context of agglutinative languages, such as Finnish whose words can have hundreds of different orthographic forms due to inflectional endings. Initial learning, based on whole word recognition, would, in such a situation, be a huge undertaking. Instead, in fully transparent writing systems, reading words or any sequence of letters forming a pronounceable item (i.e., pseudowords), is no different. Any written item can be sounded out accurately, simply by knowing the sounds of each of the letters and phonemic blending.

Although there is systematicity inherent in Chinese character orthography, traditional instruction in the classroom does not take full advantage of this. Teachers rely heavily on rote memorization, generally accomplished for reading by having children memorize characters as a paired associate learning task and for writing, by having children copy characters until they have internalized their production as a motor skill. Teachers typically demonstrate how each character is constructed, stroke by stroke on the blackboard, with students performing a repetitive copying task on worksheets at their desks. Teachers also often demonstrate how the characters are written by tracing the individual strokes with hand movements in the air, with students imitating the teacher's movements in the air at their seats. In addition, in elementary schools in Mainland China, children learn Pinyin in the first 8 weeks of school and then learn characters associated with Pinyin. During the first 2 years, all characters in language arts textbooks are annotated with Pinyin. After second grade, Pinyin only appears above new characters as a tool for decoding unfamiliar characters (Wu et al., 1999).

Internal Influences on Reading Acquisition

Developmental dyslexia is an intrinsic significant difficulty in developing reading skills in spite of adequate learning opportunities, good motivation, a normal or high level of IQ, and normal sensory abilities. Depending on the criteria, it is estimated to affect 6–17% of school age populations regardless of the language/orthography or culture (Fletcher et al., 2007: p. 105). Dyslexia is more common in males, with a gender ratio of 1.5:1 (Pennington, 2009: p. 45). It has been shown that dyslexia is neurobiological in origin, and there is strong evidence of its being heritable. Historically, the core cognitive deficits of dyslexia have been sought in many cognitive domains. However, at present there is a general consensus that dyslexia is caused by problems in linguistic skills, especially phonological processing. Individuals with dyslexia seem to have specific difficulties in processing spoken language. There may be difficulties in the ability to segment and manipulate spoken words, poor verbal short-term memory, and problems with lexical access, i.e., slow to remember/retrieve names of items. Thus, it seems that phonological representations play a part in dyslexia but their quality and/or accessibility is not well understood, even after several decades of research in dyslexia.

Dyslexia in Alphabetic Languages

A research-based definition of dyslexia states that dyslexia is characterized by difficulties in accurate and fluent word recognition, as well as poor spelling and decoding abilities (Lyon et al., 2003). Thus, the core problems of dyslexia are considered to be related to phonological processing and word-level reading, and the often observed problems in reading comprehension are secondary to the basic problem.

The research on dyslexia has a strong anglocentric history. Most of the models and theories of dyslexia are based on studies concerning English-speaking populations. Because recent cross-linguistic research on reading acquisition has shown marked differences in literacy development between alphabetic orthographies, attention has turned its focus to questions with regard to universal vs language-specific aspects of dyslexia. In a recent review of cross-linguistic research on dyslexia, Share (2008) argues that traditional emphasis on English has biased our understanding of both normal literacy development and dyslexia. The studies on neurobiological correlates of dyslexia seem to show that the neurobiological origins of dyslexia are similar across languages (Paulesu et al., 2001). Similarly, it seems that phonological processing skills predict later reading development and dyslexia across the continuum of orthographic transparency. However, the phenotype of dyslexia seems to vary depending on transparency of the orthography. It has been shown that poor accuracy as a core problem in dyslexia is, by large, specific to opaque orthographies, most notably English (Landerl et al., 1997). Instead of poor accuracy, a deficit in reading speed seems to be the most consistently observed problem in dyslexia across languages, also after the initial stages of development (Ziegler et al., 2003). In addition to being more universal, this fluency deficit seems to be also more persistent developmentally (Landerl and Wimmer, 2008). Of practical importance is the fact that among older children, fluency problems do not seem to respond well to training of phonological processing skills (Torgesen, 2005). Developing efficient means to support reading fluency, and to alleviate the reading speed deficit characteristic of dyslexia still remains a challenge for future research.

Research findings indicate that deficits in phonological processing, especially poor phonemic awareness and problems in lexical access (as reflected in problems of fluent and effortless naming), seem to be related to dyslexia in alphabetic orthographies across the continuum of transparency. However, there is research evidence to show that these linguistic skills are related to different aspects of reading development, and consequently, their role as a predictor of reading problems might vary between alphabetic orthographies. Poor phonemic awareness is supposedly more closely related to accuracy problems, and problems in lexical access – naming speed – to rate (see, e.g., Wolf and Bowers, 1999). Longitudinal studies in transparent orthographies support this notion; in German-speaking (Landerl and Wimmer, 2008) and Finnish-speaking

samples (Torppa et al., 2012), an early naming speed deficit predicted reading fluency problems, whereas phonemic awareness was predictive of inaccurate spelling. These studies also support the notion that problems in phonemic awareness and naming speed are partly independent deficits, as suggested by Wolf and Bowers (1999). However, it is worth pointing out that there are as yet no conclusive answers concerning the relation between phonemic awareness and naming speed. Although deficits in both phonemic awareness and naming speed have been shown to affect reading development in alphabetic orthographies in general, their relative relevance to orthographies that vary in transparency is still an open question (see, e.g., Ziegler et al., 2010).

Developmental Factors and Courses That Increase Risk of Compromised Learning due to Biological Reasons

The Jyväskylä Longitudinal study of Dyslexia (JLD; for review, see Lyytinen et al., 2008) examined in detail the developmental factors and courses that increase the risk of encountering difficulties during reading acquisition. Data are based on children with familial background (one parent affected) of dyslexia. Genetic factors explain the starting point (the first candidate gene of dyslexia was detected partly on the basis of the JLD data; Taipale et al., 2003). Half of those at risk who later encountered dyslexic difficulties were identified on the basis of developmental factors (delayed expressive and receptive speech) at age 1–2 years. Later indices include delayed development of phonological sensitivity and, in many cases, very slow naming speed (see Lyytinen et al., 2006; Puolakanaho et al., 2007). However, for practical, preventive purposes, it is sufficient to follow the facility to store letter names. Children who require preferably preventive intervention have difficulty in storing letter names (Lyytinen et al., 2009).

Learning Difficulties in Nonalphabetic Languages

Research has demonstrated that Chinese dyslexic children predominantly experience difficulties with accuracy and speed of word reading and spelling (Shu et al., 2006). Previous studies have demonstrated that phonological processing skills, including phonological awareness and RAN are involved in reading Chinese characters (e.g., Siok and Fletcher, 2001; Perfetti et al., 1992). The conclusion was consistent with that of alphabetic studies. However, numerous studies on Chinese children's reading development and impairment have demonstrated that visual skill and orthographic awareness (e.g., Huang and Hanley, 1995; Ho et al., 2004; Li et al., 2012; Zhang, et al., 2012a), speech perception, especially categorical perception of Mandarin Chinese tones (Zhang, et al., 2012b) and morphological awareness, including sensitivity to homophones/homographs and lexical compounding, and semantic radical awareness (e.g., Chen et al., 2009; Shu et al., 2006), as well as visual–verbal paired associate learning ability (e.g., Li et al., 2009), play significant roles in Chinese reading development.

Dissonance between Learner's Spoken Language and the Language She or He Is Learning to Read

For the most part, children's first spoken language is the same language that is being instructed in written form in school. If this is not the case – as has happened and is still happening in many countries, e.g., in Africa – whereby the learner speaks only the local language(s), but is instructed first to read English or French, the outcomes may not be good. This has been demonstrated, e.g., by the situation in Zambia. Although the formal goal of their school system is to instruct reading of the local language, the results are very poor. Largely, this is due to the fact that reading instruction has followed, from the beginning, the contents of English (Ojanen et al., 2013). A concrete example that dooms acquisition to failure is that the first step of instruction comprises recitation of English letter names when the appropriate letter names (which provide cues to the sounds) in the fully transparent Zambian are very different. A more general reason for compromised learning in multilingual environments can result from a mismatch between the language spoken in the child's natural environment and later attempts to adapt to the written language of school instruction. When a child learns to speak, she or he will become sensitized to perceive the sounds of the language spoken in the community.

Sometimes, a large variation in learning burden is encountered within one country. Spanish has a relatively consistent writing system in comparison to English. Consequently, the potential is there to foster initial instruction in the reading and writing of the native spoken language (Spanish) first, for example in the USA, with focus on the mechanics of learning to corresponding sounds and letters, and as a precursor to beginning formal instruction in reading a more complex second language, English.

The Way Forward: Computer-Assisted Learning for All Writing Environments and Developmental Prospects

In order to provide efficient support for learning to read for different types of learners in different language contexts, the above-described external and internal factors that affect learning skills need to be taken into account. In addition to traditional teacher led learning situations, technology-enhanced learning environments might provide the necessary extra support for learners. Such environments should be based on theories of reading acquisition for typical and atypical learners, relevant research findings, and, above all, provide scientific evidence as to the efficacy of such support. By utilizing technology, the basic processes needed for developing technical reading skills, learners can practice as many times as they need, the connection of good examples of spoken language items (from individual speech sounds to larger units, such as syllables, words, and sentences) to the corresponding written items. Technology has the advantage that it can provide a learning environment where learning is engaging enough (e.g., in a digital game format) and encouraging (by presenting immediate positive feedback when appropriate) for learners to practice the essential skills repeatedly – often one of the crucial factors for gaining good learning results. Also, the advantage of technology is that, if carefully designed and implemented,

individual learners can be provided with just the type of training that is appropriate at the precise stage of their skill level. This is possible, e.g., by basing the adaptation system of the software on mathematical/statistical estimations and linguistic/educational/psychological knowledge on the number and type of learning material (e.g., psycholinguistic grain sizes) that is optimal for each learner. Thus, multidisciplinary approaches to the development of such technologies are needed. One such evidence-based technological support is GraphoGame (grapholearn.info), which has been developed in Finland at the University of Jyväskylä. This technological tool is based on the main findings of 20 years of longitudinal research on dyslexia in the JLD (e.g., Lyytinen et al., 2008). By incorporating appropriate spoken language units to the corresponding written language units in a systematic manner and taking into account the nature of the orthography, such use of technology for training reading skills has been shown to have significant positive effect on learning results (e.g., Lyytinen et al., 2007; Saine et al., 2011). Encouraged by the positive findings, GraphoGame technology is currently being developed and tested in different languages using the above mentioned principles, and the results so far for developing functional reading skills have been very encouraging for alphabetic languages (Kyle et al., 2013; Ojanen et al., 2013). Using neuroimaging techniques, Brem et al. (2010) have demonstrated the neural basis of the mapping between sound and print in the very early stages of reading acquisition. For orthographically complex English, Kyle et al. (2013) showed the superior effects on learning of the more consistent rime-level units in comparison to lesser consistent phonemes.

In the alphabetic language contexts, the fluent and effortless mediation of meaning from written material may be the most challenging skill to develop for those whose learning abilities are affected by the internal factors. The challenge for GraphoGame and other technology-enhanced learning environments is to tackle the central features of nonalphabetic orthographies and establish an efficient way to provide support for building connections between the thousands of written symbols and the corresponding meanings. However, with the joint efforts of expert content providers and software developers, increasingly more affordable technological products may turn out to be a time- and place-independent and economical means to provide appropriate and targeted learning opportunities on a global level, especially to those who face challenges due to either biological (internal) or environmental (external) factors.

Conclusion

Reading is often viewed as the means of progression in modern society. The process of reading acquisition, however, is contingent on the structure and function of the language of instruction. A young reader in one country may have a much lighter workload than their peer in another. This load varies according to the number of units, their size, and the potential for ambiguity in the relationship between what is spoken and what is written. Thus, the child learning a very transparent alphabetic language can quickly latch on to the straightforward relationship between the small sound units and convert these to their consistently matching small units within written words. In contrast, a child's attempt to deploy such a simple strategy in the learning of a more opaque language, is likely to be thwarted in part by inconsistencies within these smaller-size units and thus she or he becomes more reliant on simultaneous use of more consistent larger units. All these, however, tend to pale into insignificance relative to the task of the learner of a logographic language, the acquisition of which entails larger units, in greater numbers and thus requires much longer to achieve. The burden of learning is greater still for those children who encounter difficulty with literacy acquisition – due either to inherent learning disability or externally influenced acquisition of nonnative language.

How then to support today's young reader, irrespective of the structure, function, or difficulty with the language to be learned? Technology-enhanced learning, such as the GraphoGame learning environment can assist in both first and second language learning by fostering the positive triggers that promote learning – a synthesis between the critical linguistic components specific to each language and the individual requirements of the learner – coupled with the enjoyment of learning, motivational sustenance, and positive reinforcement.

Real Estate Development

Richard Peiser, Harvard University, Cambridge, MA, USA

© 2015 Elsevier Ltd. All rights reserved.

Abstract

Real estate development is the process through which cities are built. It concerns all aspects relating to the creation of new real estate projects and adding value to existing projects – site selection, design, finance, entitlements, construction, leasing, and operations. This article addresses the steps of development, industry structure, property types, design and density, and the stages of development and real estate finance. It deals with the impact of business cycles, institutionalization of the industry, smart growth/urban sprawl, public–private development, technology, and sustainability on real estate development, both public and private. It concludes with the special social responsibilities that developers have for the built environment.

What Is Development?

Real estate development is the process of *adding value* to real estate. While most people think of development in terms of new buildings and subdivisions, development refers to any situation where value is added to a property. Developers take *development risk*, which ranges from leasing-risk associated with buying buildings with high vacancy to buying raw land with no utilities or zoning, and undertaking all the risks associated with obtaining public approvals, financing, construction, leasing, and operations of a new development project.

Developers initiate, plan, and coordinate the entire development process – buying the land, designing the product, arranging financing, obtaining public approvals, constructing the building, leasing, managing, and ultimately selling the completed project. Development is distinguished from owning and managing property because it includes at least some element of adding value. While most developers also own and manage their buildings, many real estate investors and owners buy buildings that are completed and fully leased and that do not involve adding value through some form of development.

What Distinguishes Good Development from Bad?

While there is no absolute standard to distinguish good development from bad, the test is a simple one: Does the development enhance the social welfare of the community?(Peiser, 1990) Providing new housing and office space enhances the community, but if it does so at the expense of environmentally precious resources, then on balance it may reduce the social welfare. Unfortunately, social welfare is difficult to measure – especially the indirect costs and benefits of externalities associated with the development.

Obtaining approvals for development is a political process that is increasingly long and costly. Developers used to be able to obtain their building approvals before they closed on the land, greatly reducing their risk. Today, building approvals usually take longer than the contingent-purchase time that developers can negotiate in their site acquisition contracts. Where they must take down land before they know they can build what they want to greatly increases the risk of development.

One of the biggest challenges facing city planners and council members is to create an approval process that is unbiased and gives the various stakeholders appropriate voice in the outcome. At the same time, they must do their best to streamline the process and prevent unnecessary delays and costs.

Academic and Professional Antecedents

Real estate development relates to a number of academic fields including economics, urban planning, architecture, finance, law, political science, civil engineering, and geography. Urban economics provides the foundation for understanding real estate value and how cities change over time (Mills and Hamilton, 1994; Gordon et al., 1989). Real estate finance, public finance, land use, planning, environmental law and economics, infrastructure, market analysis, demography, architecture, and landscape architecture all have significant bodies of research that contribute to the understanding of urban development and its impact on cities and countryside (see Brueggeman and Fisher (2011); DiPasquale and Wheaton (1996); Case and Shiller (1989); O'Sullivan (2012)).

Developers are generalists. They need to be conversant with many different areas. Because they are responsible for conceiving, planning, and executing the entire process, developers must have strong financial backgrounds and be excellent 'salesmen,' no matter whether they are marketing their projects, raising capital, or speaking to neighborhood groups or planning boards. Because they determine what is built and how the urban landscape appears, they should be intimately familiar with cities – what works and what does not, both from a private development perspective and from a government perspective (see Garvin, 2002).

Successful development requires knowledge of all the real estate disciplines – brokerage, finance, law, political approvals, design, construction, and management. Developers usually have several years of real estate experience before they undertake their own projects, most often in brokerage, finance and investment, or project management. Legal, architectural,

planning, and construction backgrounds also provide excellent training.

Industry Structure

Ownership

Historically, private entrepreneurs who operated in a single market have dominated the development sector. Today, large publicly held real estate investment trusts (REITs) and private equity funds are among the largest owners of property. REITs allow investors to own shares in larger pools of property in the form of a pass-through entity that distributes to the shareholders substantially all of its taxable earnings and capital gains from equity ownership (equity REITs) or mortgages (mortgage REITs) of properties. REITs invest primarily in *income-producing* property such as office buildings and apartments. Private companies still dominate the development sector, although successful development firms are becoming larger, more institutionally financed, and are operating in multiple markets. REITs and private equity real estate funds typically do little ground-up development because they have tax-driven distribution requirements and depend on operating income to create value. However, *opportunistic* and *value-added* funds and REITs often take some development risk such as leasing or rehabilitation risk to generate higher returns (see Shilling and Wurtzebach, 2010).

Altogether, real estate industry comprises almost 20% of the nation's gross domestic product (Urban Land Institute, 1997). The real estate industry is composed of many different players (see Figure 1). Developers are the entrepreneurs who create and produce real estate. They may continue to own and manage the completed buildings or they may sell them to other parties. While developers have traditionally come from the private sector in the United States, redevelopment and economic agencies often function as public developers, either directly or through public–private partnerships. Affordable housing projects are often developed by nonprofit organizations. Many corporations and public agencies including the armed forces also develop property for their own use, which is later recycled into the inventory of space available for anyone.

Each of the players is involved in a different phase of producing or managing real estate.

Property Type

Figure 2 provides a breakdown of the real estate industry by location and property type. Each location represents a different and distinct market. All property types may be found in all locations. Certain property types, however, such as major office buildings, regional malls, and major hotels are more likely to be developed in the central business district and primary suburban nodes – typically located at the intersections of major freeways and mass transit hubs – whereas industrial buildings, apartments, and shopping centers are more ubiquitous.

The real estate industry is divided into six main property types: residential, office, commercial, industrial, hospitality, and land (see Figure 2).

Each property type is virtually a separate industry, serving different purposes, markets, and customers. Although industrial warehouses, for example, may have completely different development requirements from apartments, they share a common institutional framework with respect to land, financing, legal aspects, and even construction. Still, each product is distinct, and value is created from different features. Apartments and industrial both benefit from locations near major highways. Industrial developers, however, prefer to avoid residential areas where homeowners complain about truck traffic. And apartment developers are attracted to areas with good schools, good retail services, recreation, and

Figure 1 Real Estate Industry Players. Reproduced from Peiser, R.B., Hamilton, D., 2012. Professional Real Estate Development: The ULI Guide to the Business. ULI – The Urban Land Institute, Washington, DC, p. 41.

Location	Property type
CBD	*Residential*
Inner city	*Office*
Suburbs—Wealthy	*Industrial*
Graying	*Retail*
Exurbs	*Hospitality*
Rural	*Land*

Figure 2 Understanding the real estate industry – location and property type.

other amenities that are much less important to industrial tenants.

Developers, lenders, brokers, professional service providers, and most suppliers tend to specialize in one property type. While there is considerable crossover between property types, such as electrical subcontractors who work on both office buildings and apartments, professionals develop a network of relationships over the years that favor those who concentrate on a single property type.

For-Sale versus Income-Producing Properties

A critical distinction between property types is whether they are for sale or are income producing.

For-sale property	*Income-producing property*
Land	Apartments
Single-family homes	Office
Condominiums	Retail
	Industrial
	Hotels

For-sale property is sold to a buyer after it is developed, whereas income-producing property is held for the cash flow it generates. For-sale property is valued based on how much buyers are willing to pay for enjoying the benefits of ownership – such as the consumption and investment value of living in a home in a good school district near shopping and recreation.

Income-producing property includes office, retail, rental apartments, industrial, and hotels. Values for income properties are based on the cash flow (called net operating income or NOI) they generate from leases after operating expenses are deducted. Office buildings, for example, have tenants who typically sign 3- to 10-year leases. The developer uses the lease income to obtain long-term mortgage financing.

Income properties are valued by capitalizing their NOI. Capitalization rates are determined by the market for similar properties sold and represent their NOI divided by their purchase price. For example, if a building produces an NOI of $100 000 per year, and the cap rate for similar properties sold is .08, then its value would be $1.25 million ($100 000 divided by .08). If cap rates were 9%, then it would only be worth $1.11 million ($100 000 divided by 0.09).

When the office building is sold, investors pay a premium for leases signed by large corporations who have high credit ratings. Investors may be willing to purchase a high-quality office building (excellent location and design) occupied by a major corporation such as IBM on a cap rate as low as 5%, whereas they might require an 8 or 9% cap rate for the same building with small noncredit tenants. The rental payments of a major corporation are like a bond – carrying the same credit rating as the corporation itself. In fact, the owner can sue the corporation for lost rent if the tenant defaults on the lease payment.

Design	Density
Hi rise	*80+ Dwelling units per acre*
Low rise/garden	*30–80 Dwelling units per acre*
	18–30 Dwelling units per acre
Single family attached	*8–16 Dwelling units per acre*
Single family detached	*1 or less–12 Dwelling units per acre*

Figure 3 Residential design and density.

Design and Density

The design of a building is much more important than just the way it looks. Good design is a major determinant of real estate value, not only through its appearance and quality of finish but also through the building's attractiveness and efficiency. Well-designed buildings serve the needs and preferences of a specific market in a cost-effective manner.

Building density (measured by dwelling units per acre or floor area ratio – building square footage divided by land area) determines not only how crowded or built-up a neighborhood appears but also how much the land and the building is worth. The relationship, however, is not necessarily straightforward. Even though a developer may get more residential units on a site, the net profit from building the units may be lower than for fewer units. Building costs also go up with density, and buyers may be willing to pay enough more for the lower density units that the net value created goes down as density goes up. Nonetheless, land values usually increase with density.

Densities for residential property range from one unit per two or more acres for single-family detached homes to 80–200 units per acre for a high-rise apartment building. Residential developers tend to focus either on for-sale single-family homes or income-producing apartments. Figure 3 shows the range in densities for different types of residential construction.

Commercial building densities are defined as floor-area ratios (FARs – building area divided by land area). For example, a 20 000-square-foot site where the zoning allows an FAR = 2.0 could have a building with 40 000 square feet. The building could be a two-story building covering all of the site, or a four-story building covering half the site. FARs are usually defined as rentable area and exclude parking area. However, height restrictions may make the building smaller than it otherwise would be when parking is included because it is not cost-effective to put it all underground. Downtown high-rise buildings may have FARs as high as 10–20 or higher.

The Development Process and Stages of Development

Figure 4 shows the time line of development for income-producing property. The two main periods – development and operations – involve dramatically different risks, types of financing, and activities (see Peiser and Hamilton, 2012).

Figure 4 Time line of development.

The *development period* runs from the inception of deal through the time that the building reaches stabilized occupancy (90–95% occupancy). The development period is financed by a construction loan, which covers the construction and lease-up of the building. The building is technically placed in operation when the *certificate of occupancy* is received. *Lease-up* represents a major activity of development as well as risk, and consequently is shown on the above time line as part of the development period. The operating period runs from the point in time when the building reaches stabilized occupancy to the time of sale. Once stabilized occupancy is achieved, the developer is able to obtain a long-term permanent mortgage, which is used to pay off ('take out') the construction loan (see the Section Finance, below).

The development period in Figure 4 includes the stages of predevelopment, construction, and leasing activities. The predevelopment period runs from project initiation up to the start of construction. It includes feasibility studies, site acquisition, design, and finance.

Many of the critical development decisions are made even before a developer acquires a site as part of a series of feasibility studies for the market, site, environmental conditions, and finance. Market feasibility studies help the developer identify the best location and site characteristics for a particular development (see DiPasquale and Wheaton, 1996 or Brett and Schmitz, 2009). Market feasibility differs for each product type. It includes demographic projections, income, employment, retail sales, and growth projections. The market study should conclude with estimates of demand for the product expressed in units or square feet per year in a particular location for a particular product type, as well as estimates of current and projected supply. The market study tells the developer how much space can be built, what rent to charge, and how quickly it can be absorbed by the marketplace. The market study identifies competitive properties, and helps the developer determine the best location in which to develop his or her product. It also tells the developer what the design features and amenities should be in order to attract the greatest number of customers.

While many developers focus on low vacancy rates to justify new development, the best measure of a good market is one in which the months-to-absorb the existing and new supply is within the range of 12–18 months (3 years for high-rise office buildings). This is computed by dividing the total available supply including supply under construction by the absorption per year. For example, if the total supply for competitive office space is 1 million square feet, and the annual absorption of office in that submarket is 750 000 square feet per year, the months-to-absorb the product would be 1.33 years or 16 months – a relatively healthy market.

For site selection, developers will often consider as many as 50–100 different sites in order to find five sites, which they examine in detail. From the five, they may pick one site to purchase. Development is said to be a local business because experienced developers will know information about most of the potential development sites, competition, rents, and costs in their market area.

Site Acquisition

Property acquisition occurs in three main stages: (1) putting the property under contract ('opening escrow'), (2) going hard on the earnest money deposit, and (3) closing. Purchase contracts typically run from 60 to 120 days or longer. When the buyer makes an offer, he or she places an 'earnest money deposit' of 3–5% of the total purchase price. Purchase contracts have a number of contingencies, which the developer wants to satisfy before consummating the purchase. 'Closing' is the transfer of title to the buyer and the payment of all money to the seller.

After a site is placed under contract, the developer will hire consultants to determine the site's suitability for development. The analysis should cover site characteristics, environmental status, topography, drainage, utilities (water, sewer, storm, electricity, phone, gas, and cable), as well as neighboring properties, and the chance of obtaining necessary zoning and building approvals. Once the developer is satisfied that these conditions are suitable for development, he or she will go hard on the contract. 'Going hard' means that the earnest money becomes nonrefundable – when the major contingencies such as good title and finding no environmental problems are satisfied. Since it may take longer than the typical 15- to 30-day contingency period for the developer to perform the full range of studies necessary for development, the developer will often need to ask for an extension. The developer may also do much of the investigation before even placing the property under contract or while the purchase contract is being negotiated. In a hot market, sellers are usually unwilling to extend the contingency period because other buyers are waiting in the wings.

For a large project, the feasibility period can extend several years and cost millions of dollars before the developer receives all the necessary approvals. Such projects almost always require a developer to purchase the property before many of the feasibility studies are done and long before the public approvals are in place. Such projects carry full 'entitlement' risk and represent the most risky (and potentially the highest profitable) form of development.

Design

Design includes land planning, architecture, engineering, and consulting services that go into producing completed working drawings from which the building is built. The developer often

will perform considerable preliminary design work on a property even before he or she 'goes hard' in order to determine how much space can be built, and what it will cost based on preliminary construction bids. Design drawings are used by the developer to obtain financing and political approvals. The architect prepares working drawings after the developer approves the final design. The general contractor and the subcontractors use the working drawings to bid the project and to build it.

Finance

If developers have a distinct expertise, it is their ability to raise equity and debt financing for their development activities. Development financing for income properties has two main components – construction financing to build the project, and permanent financing for operating it. Developers obtain construction financing primarily from commercial banks. Construction loans have short terms – 1–2 years, and higher interest rates – 2–3% above 'prime' – than permanent mortgages. Permanent mortgages are long term – 30 years – and have lower interest rates than construction loans because the completed property, especially if it has high-quality tenants, offers better security to the lender than one under construction. Historically, pension funds, insurance companies, and savings and loan (S&L) associations provided most of the permanent mortgage financing, but today Wall Street is heavily involved in it through securitization, commercial mortgage-backed securities, and conduit lending. Banks and mortgage brokers originate mortgages called 'conduit loans' that are packaged together, securitized, and resold as assets to investors and institutional buyers. As a result, permanent financing is highly competitive in the market place and developers and owners of property have many more sources for permanent debt than they used to.

Equity financing is the most difficult and expensive money that developers raise. It represents the developer's own cash investment in a deal, or the money raised from 'equity investors.' It is much riskier than debt financing because equity investors receive cash flow only after the mortgage payments are made during operations and after the debt is paid off when the property is sold.

For example, if a building costs $10 million altogether, the developer would typically invest 25–30% cash equity and the rest would be covered by debt. Suppose the building at stabilized occupancy (90–95% occupancy) generates $1 000 000 in NOI (rent minus operating expenses). Figure 5 shows the development cost, financing, annual operating income, and mortgage assumptions for the sample building.

In Figure 5, the simple return measures are the *overall capitalization rate* and the *cash on cash return*. The overall capitalization rate equals the NOI/total cost = $1 000 000/$10 000 000 = 10%. The *cash on cash return* equals the cash throw off/equity = $339 612/$2 500 000 = 13.58%.

Sophisticated investors focus on before-tax and after-tax *internal rates of return* (IRRs) to determine whether or not they should invest in a particular real estate deal. IRRs represent annual rates of return on equity that are comparable to returns from investing in stocks or bonds. IRR requirements depend on risk. Investors require IRRs on equity that are typically 15–20% or higher for new properties under development, whereas they may require returns as low as 9–12% for investing in a fully leased office building with high-quality tenants (see Brueggeman and Fisher (2011) for a detailed discussion of IRRs).

Construction

Developers hire general contractors to build most nonresidential buildings, whereas homebuilders and many apartment developers often do their own construction. The general contractor (or homebuilder) hires subcontractors who specialize in constructing various parts of the building such as foundations, framing, glass, granite, electrical, plumbing, heating, ventilating, and air conditioning. Legal arrangements between the developer and the contractor may take several forms depending on who bears the risk for delivering the completed building within budget and on time. Common contract arrangements include fixed price, negotiated bid, design build, fixed price with a savings clause (where savings are split between the general contractor and the developer), and time and materials. Larger contractors are often unionized while small contractors and especially those who work on residential projects and in certain 'right-to-work' states such as

Development cost

Land	$ 2 000 000
Building	$ 8 000 000
Total	$10 000 000
Financing	
Equity	$ 2 500 000
Mortgage	$ 7 500 000
Total	$10 000 000

Annual operating income

Gross rent		$ 1 500 000
Vacancy	5 percent	$ 75 000
Effecting gross income		$ 1 425 000
Less operating expenses		$ 425 000
NOI		$ 1 000 000
Less debt service		$ 660 388
Cash throw-off		$ 339 612

***Mortgage assumptions**

Mortgage amount	$7 500 000
Interest rate	8 percent
Term	30 years
Annual debt service	$660 388

Figure 5 Development cost and operating income.

Texas are typically not unionized and tend to be lower cost. During the construction phase, the developer is most concerned about delivering the building on time and under budget. Since working drawings are often incomplete or have mistakes, a nonconfrontational relationship between the developer and contractor is key to success.

Marketing, Leasing, and Sales

Marketing for a new project begins even before the developer purchases the land. In order to obtain financing for office and retail projects, the developer usually must demonstrate that tenants are interested in the property by obtaining letters of intent or signed leases on 30–50% of the property. Preleasing requirements are higher when credit markets are tight such as in the wake of the global financial crisis of 2008–09.

Developers may have in-house marketing personnel or use outside brokers to lease and sell their property. Exclusive brokerage arrangements are common whereby a brokerage firm is the developer's primary agent. Brokers work on commission, which ranges from 4 to 6% of the lease or sale value for smaller deals down to 1–2% for larger transactions in the millions of dollars. For leasing office or warehouse space, the developer will typically pay the broker whom he or she has hired as the exclusive agent for his property a 3–4% commission for signing a lease if there are no other brokers involved. The tenant often has his own broker, in which case, a higher commission will be split between the two brokers.

Successful leasing involves more than having the lowest rent for the nicest space. The developer typically gives the tenant an allowance for *tenant improvements* (TIs), which covers interior finish. For law offices in which tenant finish can run $75–$100 or more per square foot (compared to standard finish of $20–$40 per square foot), the TI allowance can make the difference in getting the law firm to sign a lease.

The Internet has replaced newspaper advertisements as the primary source of leads for apartments and most other property types. Companies use Internet listing services to place banner advertisements and featured listings, and search engine marketing experts to develop keyword search (pay-per-click) campaigns to boost traffic. Social networking sites such as Facebook are invaluable for enhancing customer service and neighborhood connectivity, although they are less useful for generating leads (Peiser and Hamilton, 2012: p. 227).

Operations

Larger developers usually have their own property management departments to handle the ongoing leasing and management of a building after it is completed. Smaller developers may hire outside firms that specialize in property management. Property management activities include repair and maintenance of the property, leasing, relations with tenants, security, building, and payment of all capital and operating expenses. Good developers give careful attention to property management because it sets the tone of relations with tenants and determines their firm's image in the market place.

Reducing turnover reduces re-leasing costs as well as renovation and cleanup required to prepare the space to be leased again. Good management stresses the importance of communications, customer service, and prompt response to repair requests in order to reduce turnover.

One of the great advantages of owning property is the ability to refinance it and take out the additional financing proceeds (the difference between the new loan and the old loan) tax free. As the NOI increases over time, savvy owners will refinance their properties regularly to take advantage of the tax-free cash they receive by obtaining larger mortgages. The operating period ends with the sale of the property to a third party. Most real estate projects generate a significant part of their financial returns from appreciation in the value of the property relative to its development or purchase cost. IRRs are highly sensitive to the length of the holding period. The shorter the holding period, the higher the IRR is. Owners try to maximize the NOI of properties they are planning to sell in order to generate the highest possible sales prices.

Current Issues and Major Trends

The real estate industry is highly cyclical. Because development can take from 1 to 5 or more years to complete a new project, depending on the difficulty of obtaining public approvals, buildings are often started when the market is hot, and completed when it is not. The real estate industry collapsed in the late 1980s to early 1990s with S&L crisis, and again in the great recession of 2007–09. "Globalization and financial innovation increased both the volume and technical complexity of investment in real estate and resulted in substantial and sustained increase in credit availability to buyers" (Peiser and Hamilton, 2012: p. 372). The great recession was the result not only of cheap and easy credit but also of the failure of regulators and policy makers to understand the increasing connection of property markets via securitization to other areas of the financial system – the so-called systemic risk.

Cycles, however, are endemic to real estate (Wheaton, 1999; Grenadier, 1995). Those who learn how to play them well are the ones who will be most profitable. Many developers and investors who bought property at bargain prices in the early 1990s made fortunes as rents and prices recovered and surpassed prerecession peaks. In the S&L crisis, many institutions went bankrupt and were taken over by the Federal Deposit Insurance Corporation and their assets were sold through the government's Resolution Trust Corporation. Bargains have been slower to materialize in the wake of the global financial crisis of 2008 because banks have not been forced to get rid of nonperforming loans.

Institutionalization of the industry: In the wake of the S&L crisis of the late 1980s, two powerful forces emerged – a vast expansion Wall Street's real estate presence primarily through securitization and commercial mortgage-backed securities, and the reemergence of REITs as a major owner of property (Sanders, 1998). By 2012, REITs had equity value of more than $430 billion, or 3.2% of the total market capitalization – up from 1% 10 years ago. While REITs and other publicly financed companies, especially national homebuilders, play an increasingly important role in real estate development and ownership, entrepreneurial developers will continue to play a significant if less dominant role in the creation of new

product. Private equity real estate funds representing institutional investors are also financing more development projects. They give larger developers who have access to institutional money a competitive advantage in competing for new projects.

Smart growth/urban sprawl: The rapid expansion of suburban growth in the last half of the twentieth century has fueled a backlash against development and *NIMBYism* (not in my backyard). 'Smart growth' addresses the problems associated with urban sprawl – congestion, loss of farmland, lack of functional open space, monotonous and boring development, and inadequate infrastructure (see Peiser, 1989). Smart growth promotes mixed land uses, walkable neighborhoods, less dependency on automobiles, environmental preservation, strong sense of place, and a range of housing opportunities. It is criticized, however, for not having greater impact on development patterns. "Buyers demand low-density development and voters oppose high-density development near them" (Rein, 2009).

Public–private development: As the regulatory process for major development projects has become more time consuming and costly, more developers are joining forces with cities, redevelopment agencies, school districts, armed forces, and other government agencies to develop property. Public–private partnerships help developers obtain lower cost financing and necessary public approvals while giving public agencies a share in the profits and the ability to deliver more public benefits such as parks, plazas, roads, sewer plants, and other infrastructure (Kotin and Peiser, 1997).

Technology: The Internet and other new technologies are having dramatic impacts on all aspects of real estate, from office building construction to shopping center functionality resulting from Internet commerce. The pace of obsolescence of old shopping centers and industrial buildings is speeding up due to changing market conditions, the great recession, and concerns about sustainability. New industrial distribution centers and 'entertainment' shopping centers are replacing them. While home offices and telecommuting have caused alarm for future office space demand and spawned new work patterns such as 'hot desks' (where employees share office space, plugging their laptop into the company computer network as they move from office to office) workers still appear to want the 'social' aspects of coming to work. Suburban corporate campuses with high-tech communications, on-site recreation, sporting facilities, and high security are being built to respond to new workplace needs and employee preferences.

The Internet is changing how developers market their properties, how they reach potential customers, how they build support for public approvals, and how they build a sense of community with tenants and residents. Rapid technological change is impacting building and construction technology, property management, reporting to investors and lenders, and financing including mortgage originations and servicing as well as equity raising.

Sustainability: Principles of sustainability – energy efficiency, lower carbon footprints, water conservation, and environmental protection – have been fully embraced by corporate and commercial real estate leaders. Corporations and real estate fund managers are making investments in projects that demonstrate high levels of sustainability in terms of operations, materials, and impact on the environment. "Energy efficiency and cost savings will remain at the core of real estate sustainability strategy, but a growing number of corporate users see the value of enhanced employee health, well-being, and productivity within workplace environments" (Simpson, 2012). Despite the trend toward ever higher standards of sustainability, developers remain cautious about spending money where they do not see a payback within 5–7 years. Nevertheless, the strong orientation in favor of greater sustainability on the part of corporate users and investors is not only raising property values for sustainable development but also giving those projects an edge in the market place.

Social Responsibility

Real estate development touches on every aspect of people's lives. It determines not only the quality of the built-form environment, but also affects the life style and social well-being of residents and workers in every community. What developers build may last a lifetime or longer. Because of their far-reaching role, developers bear a special responsibility. Most developers care deeply about the quality of their projects, not just making money. High-quality development depends as much on public sector support and services as it does on the private activities and financial resources of the developer. Since real estate involves very long-term investment, the long-term stability and continuing attractiveness of the community to new residents and firms is essential to long-term profitability for the developer. While poor development is often vilified for destroying the environment and hastening neighborhood change, good developers are responsive to neighborhood concerns and sensitive to maintaining and improving environmental conditions. As public funding has been reduced for open space and infrastructure improvements, development is often the instrument through which they are provided. As the role of developers in providing previously public-goods expands, they need to be ever more knowledgeable about the urban context in which they build and about the multitude of forces with which they must contend. The Urban Land Institute's mission statement sums up the developer's charge: "to provide responsible leadership in the use of land and in creating and sustaining thriving communities worldwide" (ULI, 2012).

Realism, in Applied Research

George Julnes, University of Baltimore, Baltimore, MD, USA

Abstract

Realism is a philosophy of science that, in its many varieties, seeks to provide adequate justification for believing that (1) the commonsense, everyday world we experience is more or less how the world really is and (2) our understanding of this world has improved across the millennia and can be expected to continue to improve, both with regard to the structures in our world (e.g., subatomic particles, as well as social structures) and the processes (e.g., underlying causal mechanisms). While most social and behavioral scientists are realists in this sense, it has proven difficult for philosophers to explicate coherent realist philosophies that can withstand criticism. As a result, there have been dozens of variants of realism proposed over the past two centuries, with the changes over time instructive for the future of realist philosophies and the implications for conducting productive social and behavioral research. One development in recent decades has been greater understanding of how humans make sense of the world, informing what has been called 'naturalized epistemology' with an explosion of cognitive and neuroscience knowledge. This, in turn, has resulted in some realist philosophers revisiting American pragmatism and promoting revised pragmatist theories that offer clearer support for social and behavioral sciences.

Realism Defined

Realism, as a philosophical approach with relevance for the social sciences, is a continuingly developing set of philosophical positions intended to justify taking seriously our commonsense experience of our world. Indeed, realism can be thought of as a position that many, or most, want to hold, with new versions emerging as older ones become seen as vulnerable to criticism. The result is a diversity of realist positions defined as much by a tension with what they oppose as by what they claim.

Common among all recent forms of realism is a critical stance regarding epistemology, acknowledging that our understanding of the real world is partial, fallible, always in revision, and never what Hilary Putnam refers to as a God's Eye View, a single, correct understanding. Another commonality concerns ontology, or the nature of our world, in that realists accept that the world exists to a large degree independent of our experience of it and that there is real causality in this world. That is, there are real underlying dynamics, some refer to mechanisms, that are responsible for what we observe (e.g., John stole the money because he was hungry and realized that no one was watching). However, the outcomes of these dynamics depend on multiple factors (e.g., John was hungry but thought he was being watched), complicating the 'constant conjunction' required by deterministic Humean models and making prediction possible only in special circumstances.

Historically, there are two main ways that realism has been understood and defined, one contrasting realism with *idealism* and the other with *nominalism*.

Reality of 'Things' in the World

When contrasted with idealism, realism is the position that the 'things' in the world exist, in some manner, independently of our perceptions of them. For example, water flowing over a waterfall creates the same erosion of the rock whether or not observed by any humans or other creatures.

Reality of Forms

When contrasted with nominalism, realism is the belief in universals, sometimes presented as Platonic forms or natural kinds. Natural kinds refer to a fundamental similarity among particulars, which "is immediately definable in terms of kind; for, things are similar when they are two of a kind" (Quine, 1991, p. 160).

For example, when we distinguish oak trees from maple trees, we are invoking the notion of natural kinds, as also when distinguishing subatomic protons and electrons. Furthermore, these groupings evolve as our understanding advances – "New groupings, hypothetically adopted at the suggestion of a growing theory, prove favorable to inductions and so become 'entrenched'" (Quine, 1991, p. 165).

When dealing with less clear-cut examples, as when categorizing different kinds of people, the question is whether we are dealing with real categories of things in the world that exist independently of our use of them, or whether we classify things simply as heuristics to simplify our communications about them. In applied research, this debate arises when we try to measure 'constructs,' such as intelligence, depression, job satisfaction, and transformational leadership. Are these constructs real or better understood as convenient labels?

Reality and Scientific Theories

These two senses of realism contribute to a debate with particular relevance to applied social research – how are we to make sense of the relationship between theory and the reality that it seeks to represent? No one currently claims that our theories correspond in some direct and absolute way to a preexisting reality; no one claims that there is no 'reality' that our theories seek to represent. It is a matter of degree. "To assert that something is somehow mind-independent is to move in the realist direction; to deny it is to move in the opposite direction. No sane position is reached at either extreme" (Honderich, 2005, p. 787). To understand the opposition to the apparent commonsense emphasis of realism, we need to appreciate both empiricist and constructivist arguments against realism.

 http://dx.doi.org/10.1016/B978-0-08-097086-8.10559-8

Empiricist Antirealism

The empiricist argument against realism is based on objecting to any statements about unobservable phenomena. Imagine two theories that explain observed regularities in terms of different unobservable mechanisms. Since the mechanisms are unobservable, "no scientific evidence can bear on the question of which of these theories provides the correct account of observable phenomena…it follows that scientific evidence can never decide the question between theories of unobservable phenomena and knowledge of unobservable phenomena is thus impossible" (Boyd, 1991, pp. 196–197).

Constructivist Antirealism

The constructivist argument against realism is more subtle. Given that every aspect of the scientific enterprise is theory dependent (theory provides the frame in which we judge the acceptability of methodology, theory, and even the nature of observation), science can work only if what is being studied is also theory dependent.

Varieties of Realism in History

Most scholars of realist philosophy comment on its diversity. For example, Harre titled a book *Varieties of Realism*; Putnam named one *The Many Faces of Realism*. This diversity results in realism being the dominant perspective but also feeling marginalized. In that the history of realism is one of overcoming challenges, we can see an evolution in the balance between direct perception of the world and perception being only indirect, conditioned by what humans bring to the experience. As such, all realist positions described here (see O'Shea, 2008; Reese, 1980; for more background on each of these) are an attempted balance between what is called naïve realism, the view that reality is exactly like our perception of it, and idealism.

Locke's Representational Realism

John Locke's theory of primary and secondary properties was an early attempt to reconcile an understanding that there are things in the world, our senses provide sense data, which are then organized into perceptions. This is a realist theory in that the things of the world exist independently of human experience and understanding, but it avoids the problems of naïve realism by having perception mediated by ideas.

Commonsense Realism of Thomas Reid

Writing in the second half of the eighteenth century and reacting to the theory of knowledge of the British empiricists (no knowledge of unobservables), Reid ascribed more trustworthiness to commonsense descriptions than to the philosophical abstractions of Hume and Berkeley. Similarly, our intuitions of ethics were to be trusted over philosophical analyses.

New Realism

Near the beginning of the twentieth century, a group of philosophers (Holt, Marvin, Montague, Perry, Pitkin, and Spaulding) promoted a position called 'new realism' that sought to counter prevalent interest in neo-Hegelian idealism. Making use of work by G.E. Moore (e.g., "The Refutation of Idealism," 1903), this group published an initial article in 1910 and a book in 1912 titled *The New Realism* (Holt et al.). Rejecting both idealism and materialism, this group argued for a realism that "is opposed to subjectivism or epistemological idealism which denies that things can exist apart from an experience of them, or independently of the cognitive relation" (Holt et al., 1910, p. 396). However, this entailed something of a direct realism. "For the new realists in general, there is an act of cognition and an object or datum directly cognized, without any intermediary ideas or perceptions of the sort proposed by traditional representational or indirect realist (Descartes, Locke)" (O'Shea, 2008, pp. 218–219).

American Critical Realism

In 1920, the book *Essays in Critical Realism* (coauthored by the US philosophers Durant Drake, Arthur O. Lovejoy, James Bissett Pratt, Arthur K. Rogers, George Santayana, and Roy Wood Sellars) presented critical realism as an American movement of a direct realism that also addressed 'the nature and mechanism of knowing' to allow for a critical stance. Critical realism hence was intended, in part, to counter the new realists, who, with their near identification of the things of the world and our sense-datum, were seen as insufficiently 'critical' in framing the strengths and limits of human understanding.

Further developing this critical stance, Roy Wood Sellars (who published a book titled *Critical Realism* in 1916) labeled his variant 'emergent realism' to emphasize the nonreductionist nature of his framing of causality. Specifically, "Sellars, like the British emergentists, made use of the 'layered model' of reality, one according to which entities of the world are ordered in a hierarchy of increasingly complex 'levels,' with humans and higher-organisms, and their emergent characteristics of life and mentality, occupying the higher levels" (Kim, 2003, p. 89).

Sellars was also a proponent of a robust naturalism that appears in all subsequent realist theories. Indeed, his books "outline a conception of the human being as a complex product of organic evolution, resulting in a dynamic and multi-leveled cognitive and causal relationship to its environment" (O'Shea, 2008, p. 220). In line with this naturalist perspective, he also authored the first draft of the 'Humanist Manifesto' of 1933. Hence, we see that the critical realist perspective contained fairly modern notions of human understanding being based on evolved cognitive capacities that were, nevertheless, constrained by what evolution did not provide. While this naturalist perspective was overshadowed by analytic philosophy for much of the middle of the twentieth century, these insights provided the foundation for the scientific realism that was developed in the 1950s and continues to this day.

Current Realist Perspectives

As noted above, the variety of realist accounts is the result of something akin to natural selection – theories overly vulnerable to criticism do not 'survive,' so that realist theories still

being proposed are those that have yet to succumb. The overarching frame for recent approaches is scientific realism, which contributes in large measure by being an alternative to positivism (with logical empiricism being a recent variant) and constructivism (we 'construct' reality and know it only through our constructions). As such, the general scientific realist frame is presented first, followed by variants offered by Hilary Putnam and Roy Bhaskar.

Scientific Realism

In the 1950s Wilfrid Sellars, son of Roy Wood Sellars, promoted scientific realism as more consistent with the world that modern science at that time was presenting. "The nonreductive materialism that was being sketched in original ways by Roy Wood Sellars should certainly be credited… with anticipating many developments later in the century. But it was the tools provided by the various phases of the logical and linguistic turn in the analytic tradition that enabled Wilfrid Sellars to develop more powerful and substantive theories on just how…the perceptual, conceptual, and normative dimensions of the perceptually experienced world or *manifest image* of persons-in-the-world are to be successfully integrated with the comprehensively causal and naturalistic picture of physical nature that is projected in our ongoing scientific image of that same world" (O'Shea, 2008, p. 233).

In its recent form, scientific realism is contrasted with social constructivism as the primary alternatives for a philosophy of science. "According to realists, when a well-confirmed scientific theory *appears* to describe unobservable 'theoretical entities,' it is almost always appropriate to think of its 'theoretical terms' as *really* referring to real unobservable features of the world, *which exist independently of our theorizing about them*" (Boyd, 1991, p. 11). As with other realist theories, it is this insistence on the independent existence of the reality being described that distinguishes realism from social constructivists. This is not to say that social constructivists are trapped in the empty claim that there is no reality, only that everything the realist thinks is 'real' is instead socially constructed. "Socially constructed causal and metaphysical phenomena are, according to the constructivist, real: they are as real as anything scientists can study ever gets" (Boyd, 1991, p. 13).

Elaborating these points, Boyd (1991, p. 195) presents four basic theses of scientific realism; in brief, scientific theories (1) "should be interpreted 'realistically'"; (2) "are confirmable *and in fact often confirmed* as approximately true by ordinary scientific evidence"; (3) progress with "successively more accurate approximations to the truth about both observable and unobservable phenomena"; and (4) describe a reality that "is largely independent of our thoughts or theoretical commitments."

Causal Explanation

Consistent with the philosophy of science emphasis, scientific realism addressed the nature of causal explanation. An early version of this was C.S. Peirce's concept of 'abduction,' which involves the probabilistic inference of observing something surprising, considering possible explanations, and then accepting, at least tentatively, the explanation that best fits what is known. This form of knowing was developed further in scientific realism in the 1950s, with Hanson promoting retroduction as an updated version of abduction. This is currently presented as a natural human tendency to seek an 'inference to the best explanation.'

Naturalized Epistemology

An additional emphasis of scientific realism, continuing to be developed today, is called natural epistemology. One aspect of this is the recognition that many prior philosophical debates on knowing, or epistemology, took place without any interest in or understanding of how humans actually make sense of the world. If a type of inference did not satisfy the demands of deductive logic, then the knowing that resulted was second-rate and suspect. In contrast, naturalized epistemology recognizes that humans have evolved to be reasonably good at making sense of the world, and that these natural capacities should be respected. "The old epistemology aspired to contain, in a sense, natural science; it would construct it somehow from sense data. Epistemology in its new setting, conversely, is contained in natural science, as a chapter of psychology" (Quine, 1994, p. 25). This emphasis on evolved natural capacities supports arguments for trusting our commonsense understanding of the world.

Putnam's Internal Realism

Hilary Putnam has been a prominent American realist for the past half-century. Having studied under the noted scientific realist Hans Reichenbach, Putnam developed a variant (labeled 'internal realism'), understood as a type of commonsense realism.

Commonsense Realism

One commonsense aspect of Putnam's realism concerns the goal regarding our understanding of the world – rather than advancing knowledge claims as being 'justified' in a formal sense, he uses Dewey's term 'warranted assertibility.' From this, his realist argument includes: "In ordinary circumstances, there is usually a fact of the matter as to whether the statements people make are warranted or not…[and yet] Our norms and standards of warranted assertibility are historical products; they evolve in time" (1990, p. 21). This is a realist view that embraces our commonsense world but also is skeptical of any formal, final criteria for justifying acceptance of specific knowledge claims. In addition, the commonsense stance also involves 'antiformalism,' the view that our formal logics and formal accounts of knowing can be useful guides for how we approach the world "but it manifests itself in a sustained critique of the idea that formal models, in particular, systems of symbolic logic, rule books of inductive logic, formalizations of scientific theories, etc. – describe a condition to which rational thought either can or should aspire" (Putnam, 1995, p. 63).

Possibility of Progress

It is possible to 'get it right' in our understanding without 'absolutely getting it right.' So, for Putnam, it is appropriate to conclude "Newton got it right when he said that the tides are caused by the gravitational pull of the moon and the sun" (1990, p. 131) without having to claim that the Newtonian worldview is correct or is a limiting case of the worldview

presented in quantum mechanics. The same can be said for what quantum mechanics gets right – we have every reason to expect our understanding to continue to develop.

As for whether it is appropriate to hold onto the modernist faith in progress, Putnam notes that we cannot prove that faith "but our action is 'fantastic, directed to empty, imaginary ends' if we do not postulate the possibility of progress" (Putnam, 1990, p. 191). On the other hand, this need not suggest that our understanding is converging on some God's Eye View of the world. "There is no more evidence that science converges to one final world-view than there is that literature or morality converge to one final world-view" (p. 130).

Fact–Value Relationship

Putnam rejects the notion of a fact–value dichotomy (though does accept that it can be useful to note distinctions between them that can be illuminating). As such, he also accepts that it is possible to talk about some value judgments being more warranted than others. "As a being who makes value judgments every day, I am *of course* committed to the idea that there are true value judgments; *what must be the case if there are to be true value judgments?* In what kind of world can there be true value judgments?" (Putnam, 1995, p. 43).

Bhaskar's Critical Realism

Another current variant of scientific realism was developed by Roy Bhaskar and his dissertation mentor, Rom Harre. Bhaskar's realism was developed first (1975) as *transcendental realism*, providing a more persuasive realist foundation for the natural sciences. He subsequently elaborated his theory to include *critical naturalism* for the social sciences, emphasizing a reality that is differentiated and stratified. Later commentators, whether aware or not of the American tradition of critical realism, concatenated transcendental realism and critical naturalism into 'critical realism,' and the name stuck.

Transcendental Realism

Bhaskar characterizes his basic position as transcendental realism, in homage and contrast to Kant's transcendental idealism, and states that it "regards the objects of knowledge as the structures and mechanisms that generate phenomena" (1975, p. 25). This is consistent with other variants of realism, as is the claim that "critical realism is realist because it holds, contra postmodernism and social constructionism, that research is about gaining knowledge of a reality that exists independently of our representations of it" (Cruickshank, 2003, p. 3).

One concept central to the ontology of transcendental realism is the notion of 'stratified' layers of our world. At the deepest level (the domain of 'real') are real structures and mechanisms. These underlying mechanisms result in 'events' in the world that are potentially observable in the intermediate level, the domain of 'actual.' At the surface, 'empirical' level, we have 'experiences' of the world and make sense of observed patterns.

Further, the variation, or 'differentiation,' we see in the world, the lack of 'constant conjunction' of cause and effect, arises because "real structures exist independently of and are often out of phase with the actual patterns of events. Indeed it is only because of the latter that we need to perform experiments and only because of the former that we can make sense of our performances of them" (Bhaskar, 1975, p. 13). That is, there are meaningful patterns in reality that justify our efforts to distinguish and explain them, but the underlying mechanisms that we want to understand are not expected to yield the same effects in different contexts.

Critical Naturalism

Elaborating his vision to the social sciences, Bhaskar addressed the complexities of open systems with a theory he called critical naturalism, presented in *The Possibility of Naturalism* (1979). Central to this vision is a dialectic between the sociological structures and psychological agency: "critical realists argue: (1) that structure and agency need to be linked, and that we must avoid putting all the explanatory weight on structures or individuals, as this results in determinism and an inability to explain individuals' social relationships" (Cruickshank, 2003, p. 3).

This approach qualifies as a critical one because of its emphasis on critical dialogue. "Critical realism is critical, as regards methodology, because it hold that the concepts which inform the meta-theory that defines structure and agency can only be developed via a critical dialogue with alternative social ontologies" (Cruickshank, 2003, p. 3). Further, there is also a normative claim, building on Marxist thought that justifies a moral vision of the world. "Critical realism is also critical in a political as well as a methodological sense…to enable the move from facts to values…to explore how existing social, political and economic relations create inequality, and turn on exploitation, in order to develop a normative critique against those relations" (Cruickshank, 2003, p. 3).

Another concept important in transcendental realism but particularly so in critical naturalism is 'emergent order,' the idea that phenomena cannot be reduced to what is understood of lower-order understanding. "It follow from this that the operations of the higher level cannot be accounted for solely by the laws governing the lower level in which we might say the higher-order level is 'rooted' and from which we might say it was 'emergent'" (Bhaskar, 1975, p. 113). This allows us to be informed by lower-order dynamics but not to be constrained by them for our understanding.

Implications of Realism for Social and Behavioral Sciences

The most cited value of realist philosophy for social sciences is the warrant that it provides to avoid choosing sides in some ongoing methodological debates, offering instead a position that, potentially, can support some reconciliation. That is, most social scientists do not embrace standard versions of either positivism or constructivism, instead believing that there is a real world that we want to, and can to some degree, understand. For example, Julnes and Mark (1998, p. 36) ask "Are we to choose, in Bhaskar's words, between either a conceptually impoverished and deconceptualizing empiricism, or a hermeneutics drained of causal import and impervious to empirical controls (1989a, p. 12)?…[instead] we promote an alternative based on the philosophical paradigm known as realism." Similarly, Meehl (1986, p. 322) noted

that "As to realism, I have never met any scientist who, when doing science, held to a phenomenalist or idealist view; and I cannot force myself to take a nonrealist view seriously even when I work at it."

Implications for Ontology and Epistemology

As stated above, the realist ontology begins with the belief that the real world is approximately what we experience, and its epistemology with belief in having fallible, constructed knowledge of a real world. Meehl (1986, p. 322) speaks for this commonsense view in stating, "So I begin with the presupposition that the external world is really there, there is a difference between the world and my view of it, and the business of science is to get my view in harmony with the way the world really is to the extent that is possible."

Recent realist perspectives also acknowledge the difference between closed systems and open systems, wherein the open systems of interest to social and behavioral sciences involve underlying mechanisms operating in complex, changing environments such that (1) variations in contexts can influence expression of those mechanisms and (2) emergent phenomena will result that cannot be reduced directly to the dynamics of less complex phenomena (Julnes and Mark, 1998). These two points underlie Don Campbell's *Evolutionary Epistemology* (1974) and, hence, the position referred to as *Evolutionary Critical Realism* in Cook and Campbell (1979, pp. 28–30). As such, there will be few 'universal laws,' and the perceived regularity of observed patterns will depend on our understanding of the mechanisms underlying them and the ways in which those mechanisms are influenced by contexts.

Implications for Methodology

There are different views of whether there is a 'realist methodology.' For example, Pawson and Tilley (1997) develop a specific methodology for what they call 'realistic evaluation' that is based on identifying patterns of mechanism (M) that operate differentially in different contexts (C) to yield observed outcomes (O). However, in addition to emphasizing a qualitative approach to understanding how mechanisms are triggered in specific contexts (referred to as the CMO framework), they also acknowledge some value for pluralism of methodology. Similarly, others (e.g., Yeung, 1997) criticize the notion that there is a 'realist methodology.'

We can, however, discern a general logic suggested by realist views. The logic is an iterative one that involves the process of abduction that Peirce explicated over a century ago and which has since been elaborated as pattern matching – identifying potential mechanisms responsible for observed regularities, testing out those mechanisms, and then developing ever more refined understandings of mechanisms and testing those.

Pattern Matching

Pattern matching is the general realist process promoted by Campbell for supporting conclusions about causal mechanisms. It is an iterative process, moving from theorizing to testing to theorizing, and so on, but it is useful to highlight the processes of both retroduction and competitive elaboration.

Retroduction: Inferring Underlying Mechanisms

Peirce's 'abduction,' reframed by Hanson and others as retroduction, refers to the natural human capacity for speculating about mechanisms responsible for observed regularities and accepting provisionally the mechanism most consistent with the observed regularities. This has been a consistent feature of realist theories for a century and remains foundational still.

Competitive Elaboration: Testing Presumed Mechanisms

Competitive elaboration is a logic rather than a specific method and "refers to the process by which alternative explanations (mechanisms) – whether alternative program theories or validity threats – are ruled out" (Mark et al., 2000, p. 256).

An important point to make is that this process is used in some form by most, if not all, social scientists. For example, when asked how to improve testing theories in observational studies, "Sir Ronald Fisher replied, 'Make your theories elaborate'…[meaning that] when constructing a causal hypothesis one should envisage as many different consequences of the truth as possible, and plan observational studies to discover whether each of these consequences is found to hold" (Cochran, 1965; cited in Mark et al., 2000, pp. 254–255).

As an example of this approach, consider Milgram's series of studies on the factors, or mechanisms, responsible for the willingness of participants to increase what they believed was the voltage of an electric shock applied to another participant. Through retroduction, one posited mechanism was 'identification with the experimenter' and so, in line with competitive elaboration, "one set of studies varied the exposure to the experimenter, with some subjects having the experimenter present during the experiment and others only meeting the experimenter at the beginning of the experiment" (Julnes, 2005, p. 888).

Future Directions

Realism will continue to be a dominant perspective as a philosophy of science, particularly in the social and behavioral sciences. It will maintain this position in part because people want to believe in realism. In the process, however, it will continue to evolve, both in response to criticism and in response to advances in our understanding.

One form of development involves incorporating new phenomena into the perspective. For example, Bhashkar has continued to elaborate his theory, moving beyond his initial focus on transcendental realism and critical naturalism to emphasize the emancipatory imperative of critical realism (developed around 1986–94 and referred to as 'dialectical critical realism') and later its spiritual aspects ('transcendental dialectical critical realism,' developed around 1994–2000).

Another form of development comes from developing new technology that yields patterns with implications for our ways of knowing and, hence, for the types of realism that seem most consistent with such ways of knowing. Two aspects of this form of development can be seen in the increasingly productive fields of cognitive science and neuroscience. The understanding that is resulting from this work is also increasing interest in American pragmatism, a perspective developed over a century ago but increasingly relevant today.

Cognitive science and Neuroscience

Debates about how to conduct research (e.g., regarding the contrasting strengths and limitations of qualitative and quantitative knowing) will increasingly be framed in terms of our understanding of cognitive science and neuroscience. For example, in the controversy over the appropriate roles for 'rigorous' quantitative designs for causal impact conclusions, research on causal cognition in children showed that they routinely make use of two approaches to understanding causal relations – one, depending on the covariation of events that is the bedrock of quantitative methods and, the other, a sort of a 'folk psychological domain,' that involves the intentionality of actions that makes up the agency studied with qualitative methods. That is, evidence about our evolved capacities for causal understanding suggests two very different evolved capacities that, not surprisingly, have resulted in two sets of evolved methodological tools to support those capacities.

Similarly, neurological research has shown that different parts of the brain are involved in different aspects of valuing. When people are thinking about receiving an immediate reward, the 'emotional' area of the brain (midbrain dopamine system, the nucleus accumbens) is active; when thinking about long-term rewards, the 'rational' prefrontal cortex area is active. We can expect that our efforts to understand value judgments will lead to new methodologies for applied social sciences like program evaluation and policy analysis, some methods supporting our rational, analytical valuing and others our more holistic valuing.

Pragmatism: Theories and Methods as Tools for Assisted Sensemaking

As discussed above, many of the foundations of recent realist thinking, such as Bhaskar's retroduction and evolutionary epistemology, originally were developed by people like Peirce, James, and Dewey who are grouped as early pragmatists (also, in the history of psychology James and Dewey are grouped in the paradigm now known as functionalism, distinguishing it from the earlier structuralist paradigm). To see how this fits with realist theories, "remember the evolutionary roots of pragmatism, wherin our cognitive abilities are viewed as having evolved to solve problems" (Julnes, 2012, p. 112). Once our theories and methods are viewed as tools, we are freed to some degree from dependence on formal philosophic positions to guide the development of the social and behavioral sciences. As Putnam explains, having evolved into a greater appreciation of pragmatism (in part, as he notes, due to the work of his wife, Ruth Anna Putnam) he has come to see that it contains insights that seem 'lastingly right' and which have implications for both realism and the antirealism that it opposes. He expresses appreciation of the "pluralism and thoroughgoing holism which are ubiquitous in Pragmatist writing" (1995, p. xii) and notes that viewing "fact, theory, value and interpretation as interpenetrating undermines a certain sort of metaphysical realism" and also "undermines fashionable versions of antirealism and 'postmodernism'" (1995, p. xii). As this vision of pragmatism develops (and it escapes the discredited one-line description that it is based on the belief that "if it works, it must be 'true'"), new versions of realism will begin to merge with it and will be successful to the extent that they support more productive work in the social and behavioral sciences.

Realism/Neorealism

Arthur A Stein, University of California, Los Angeles, CA, USA

Abstract

Realism is an approach to international politics that has a long historical tradition and numerous variants. It focuses on the actual state of the world, takes as given that the key actors are self-interested states, and that they interact in an anarchic setting, one in which there is no central authority to enforce order. As a result, states seek power and what emerges is a conflict-ridden world in which the balance of power is the only basis for order. The perspective has problems and limitations but few analyze international politics without focusing on the distribution of power.

Varieties of Realism in International Politics

Realism is a broad approach to conceptualizing international politics. As with any broad approach, it has intellectual antagonists, internal disagreements generating subtle distinctions among types of realism, and experiences recurrent efforts at reformulation.

Realism is a tenet that views the world as it is, and not in terms of an unrealized ideal. It emphasizes the constraints of the real world and the need for pragmatism and prudence. Applied to international politics, realism sees a conflict-ridden world of states concerned preeminently with their security, struggling for advantage, sometimes seeking dominance, and therefore pursuing power as the means to assure these. Realists therefore see the distribution of power as the major determinant of state behavior and international stability. Within this broad rubric, realists have developed alternative formulations, emphases, and distinctions, and others have appropriated aspects of realism and conjoined it with a plethora of other perspectives.

The Realist Vision

The realist vision of international politics holds that states interact in an anarchical international environment in which survival is uncertain. Because power is the key requisite for survival, states define their interests in terms of power and constantly assess their strength relative to that of others. What emerges from their interaction is a balance of power that is the sole basis for order, regularity, and stability in international politics.

Realism emphasizes the competitive and conflictual nature of international politics. States either constantly prepare for war or are actually at war with one another. Fearing adverse shifts in the balance of power, they respond with balancing behavior, either through internal mobilization and, should that prove inadequate, with external alignment. Self-reliance is preferred in such a system of self-help, but allying with others to confront a common threat may be temporarily necessary. Cooperation is thus short-lived, lasting only as long as the common threat, and is a function of common interests and not common values or ideology. Realism can therefore readily explain alliances between wholly antithetical political systems, such as the Nazi–Soviet pact of 1939. The mobilization and alignment that result in response to adverse shifts in the balance of power return the system to a state of balance. Hence, balances of power recur and reemerge in international politics.

Realist Assumptions

Realism is a statist perspective, for it assumes states to be the key actors in the international system. It excludes multinational corporations, nongovernmental organizations, and a variety of transnational and subnational entities that matter only to the extent that they affect states.

The theory assumes that states face recurrent threats and challenges in the international system. Power, especially military power, is the basis of both threats to a state and to its ability to assure its survival. Although some acknowledge a variety of forms of power, the overwhelming focus is on military capabilities, their distribution and those material resources that make them possible.

Realism presumes survival and its requisites to be the highest priority of states, indeed, their very reason for being (*raison d'etat*). States value security considerations above all and respond to the imperatives of the international system. The primacy of security implies that other policies, including foreign economic ones, reflect considerations of international power politics. Other state objectives, such as ideological ones, are inherently secondary. They are only pursued when security is assured, and they are readily abandoned when security is threatened.

Realism Deemphasizes

For realists, international law and international organizations are largely irrelevant to international politics. Both reflect the interests of powerful states, for in international politics might makes right, and international institutions do not constrain great powers but merely provide additional venues for the exercise of power. At most, both play a role only in matters of low politics, in regulating transportation, communication, and economic exchange, for example, and not in matters of high politics, especially military security.

Realists also consider the requisites of survival to dominate any moral considerations. The requisites of survival are more important than any ethical considerations. Indeed, realists transform necessity into a moral imperative.

 http://dx.doi.org/10.1016/B978-0-08-097086-8.93119-2

Realism downplays the role of domestic politics. It treats states as unitary actors that are functionally equivalent to one another, and the constraints imposed by the international system generate similar behavior even by dissimilar states. The international system once consisted largely of monarchies and then of authoritarian and military governments, and is now increasingly composed of democratic states. For realists, however, it continues to function in the same way. Differences in the internal composition of states do not matter, except if they affect relative power.

Self-reliance precludes states from allowing the development of any division of labor or any interdependence regarding the requisites of state survival. Small states may have no choice but to rely on others, but great powers do have such choices and thus do not allow the emergence of any meaningful interdependence.

Realism as Equilibrium Theory

The balance of power is an equilibrium theory. The security policies of nations result in a balance of power among states. The equilibrium can be disturbed, but only by exogenous shocks, ones outside the model. The disturbance then sets in motion forces that return the system to a new equilibrium. The implosion of the Soviet Union, for example, disturbed the balance of international power, but was an event outside the model and inexplicable by it. But realism does purport to explain the set of forces that then would come into play to return the system to equilibrium. For some, a balance of power is something states seek; for others, it is an unintended result.

Put this way, balance of power theory functions like Adam Smith's invisible hand in creating an unintended outcome. For Smith, the self-interested behavior of producers in a competitive market generated the best price for consumers. In international politics, the pursuit of national interest and the struggle for power in an anarchical system create a peaceful stable order. It is not the search for peace but the search for security that creates this stability. The preparation for war assures peace.

Realism's Historical Roots

Realism traces its lineage to Thucydides, who argued that his *History of the Peloponnesian War* (1996) provided the one and true explanation of the war: the growth of Athenian power and the fear this struck in Sparta. Thucydides argued that preceding incidents and specific complaints notwithstanding, the true cause was a shift in the balance of power.

As important to current realist formulations is the work of Thomas Hobbes, who translated Thucydides into English and argued (in *Leviathan*) that the state of nature, which he characterized as a war of all against all, is one in which war and preparation for war are a constant. Conflict is limited within societies by the creation of the Leviathan, a coercive state. For modern realists, who distinguish international from domestic politics, international relations remains an anarchic realm; there is no Leviathan and the war of all against all endures.

Realism dominated the study of international relations in the middle of the twentieth century as the world came to grips with the occurrence of the Second World War and the failure of both international law and international organizations to prevent it. Hans Morgenthau's (1948) influential formulation of realism drew upon psychology and rooted realism in a human nature presumed to be inherently aggressive and in a view of individuals as power seeking.

Beginning in the 1950s and increasingly in the 1970s, an alternative realist version emerged. It coincided with the rise of (and often appropriated the terms of) systems thinking in the 1950s and structuralism in the 1970s. This variant rejected basing realism in any theory of human nature or any internalized commitment to a balance of power. This neorealist formulation did not posit any individual or collective propensity toward power maximization per se. Neorealism was a purely systemic theory, one that focused on the characteristics of the international system structure, rather than the nature of individuals or states. Rather, it posited a minimalist concern with survival in an anarchic setting as the only necessary conditions. The anarchic system, the absence of hierarchy assured a struggle for survival and an emphasis on power. All states caught in an anarchic structure have no choice but to arm themselves in preparation for the possibility of war and must assiduously guard their relative power. Neorealism or structural realism firmly rooted the problem of international politics in the international system and not in the nature of individuals or states.

Realism has a core set of assumptions and relaxing any one opens the door to an alternative approach. Neorealists maintain a pristine structural approach that abjures discussion of foreign policy. They provide a theory of international politics and not one of foreign policy. Others have returned to what they describe as a more classical perspective and developed a neoclassical realism that aspires to provide a theory of foreign policy, maintaining the international system as a key independent variable but including domestic constraints and elite perceptions as important intervening variables.

The Realist View of History

For realists, history consists of the rise and fall of great powers and of changes in the distribution of power in the international system. Much like economic structures are characterized by the distribution of firms (monopoly, duopoly, oligopoly, and a competitive market), the international system is characterized by the distribution of power, and more specifically the number of great powers. Multipolarity is a system of three or more powers, bipolarity is a system of two great powers, and unipolarity (or hegemony) is a system with one dominant power. Changes in the distribution of power constitute major break points in history and determine the structure of the international system. The multipolarity of the nineteenth and early twentieth century is contrasted with the bipolarity of the Cold War and contrasted with the unipolarity of the post-Cold War world. Historical periods are characterized by the distribution of power in the system, and the challenge of international politics in any era is that of dealing with changes in the relative power of great powers. The end of the nineteenth and beginning of the twentieth century had to deal with the rise of German power, and the current age is dominated by a focus on the rise of Chinese power.

This characterization of the international politics of the last century contrasts with those that emphasize the role of ideological competition and conflict. Diplomatic histories of the last century invariably focus on ideological conflict. They note the conflict between liberalism, fascism, and communism as the dominant feature of both domestic and international politics. The emergence of a Communist Russia is seen as a central feature shaping international politics from 1917 to 1989. Nazism and fascism are deemed to have posed a challenge to international order in the 1930s and 1940s. The Cold War that followed the end of World War II is not simply a case of bipolarity but to be understood as a conflict between Communism and the liberal west. Finally, the collapse of the Soviet Union is not merely the collapse of one of the two superpowers in a bipolar world but the end of the Communist challenge and the triumph of liberalism. For realists, however, ideological conflict was merely epiphenomenal to changes in the set of great powers and the distribution of power in the international system.

Disagreements and Debates

Despite the consensus in emphasizing states as the central actors, security as their prime concern, and power as their key instrumentality, there is some confusion and disagreement in the core of realist thought. First, there is disagreement about the level of analysis of realist thought and the nature of both its dependent and independent variables. For neorealists especially, realism is a purely systemic argument. It merely explains the recurrence of balances of power in the international system. It is a theory of international politics and not of foreign policy. It cannot explain the foreign policy of any particular state but merely the tendency of the system to arrive at a balance of power. For others, harking back to a classical realism, and dubbing themselves neoclassical or neotraditional realists, the emphases on power and interest imply particular foreign policies in particular circumstances.

A second related source of confusion and disagreement is whether the theory is positive or normative. Realists typically argue that theirs is a positive theory of how the system actually works (an iron law of international politics), yet many (including structural realists) have also used realist precepts to criticize the foreign policies of specific countries. Realists, for example, criticized US military involvement in the Vietnam War in the 1960s and in the Iraq War of 2003. Yet, if realism can be used to criticize extant policy, then it is inadequate as an explanation of that policy. Moreover, if it provides no theory of foreign policy then it should hardly be used as a basis for criticizing a particular foreign policy.

That politicians adopted the argument also led to disagreement. First, the term balance of power has come to be used loosely and applied to virtually every configuration of power. Second, there is a disagreement between scholars as to whether realism operates through intention (states must aim for a balance of power) or irrespective of it (as an unintended consequence).

Disagreement about the nature of the dependent variable (does realism explain foreign policy or just international politics) is matched by disagreement on the independent variable side as well. Although all scholars emphasize the role of power and the distribution of power, there are those (neoclassical realists) who see the impact of power as mediated by domestic politics. Thus they do not argue that dissimilar states will always respond in the same way to a particular distribution of power.

Finally, there is even a little disagreement about the core proposition of balance of power theory, that the workings of the system mean that balances recur and are the basis of international stability. First, there are different balanced configurations of power and there is some disagreement about the relative stability of different configurations of power, about whether bipolar or multipolar international systems are more stable. Most scholars argue that bipolarity is more stable because states readily respond to adverse shifts in the balance of power. In contrast, in multipolar systems, states will pass the buck in the hope that others will deal with adverse changes in the balance. This delays the return to balance and stability. Multipolar systems are thus thought to be more war-prone and unstable. By and large this is the consensus, though there is some disagreement on this point.

Most realists, as balance of power theorists, agree that the international system tends toward balance (though more predictably and more quickly in some settings than others) and that hegemony and unipolarity are therefore not possible or sustainable. Any state aiming for global domination generates countervailing coalitions of power and thus attempts to achieve hegemony have historically failed. Yet, there are those scholars who hold that the system tends toward power preponderance rather than balance, and that hegemony is stable but that a balance of power is not. This has played out in the last two decades in competing predictions of the post-Cold War world. Following the collapse of the Soviet Union and the end of the bipolar order, balance of power realists argued that US hegemony, or global unipolarity, would be short-lived. Coalitions that had been built to contain Soviet power would come apart once the threat that had been the basis for their existence disappeared. Moreover, the US would succumb to imperial temptation, and even if not, others would balance against US power and multipolarity would soon emerge. In contrast, others have argued that unipolarity is stable and sustainable, either because they believe that preponderance is generically stable or because they believe that US hegemony differs from prior attempts to achieve global domination.

A sustained debate has emerged within realism between offensive and defensive realists. The former argue that anarchy and the concern with security, and therefore, power result in states that are power maximizers. All states are revisionists, assertive expansionists seeking to maximize their power relative to others. Like classical realists, they argue that states are power maximizers. But they do not root this in any individual will to power, but in the requisites of survival in an anarchic world. In contrast, defensive realists emphasize that security seeking leads states to respond to adverse shifts in the balance of power but also leads them to forgo seeking advantage over others. Security-seeking states recognize the existence of a security dilemma, in which a state's search for military superiority will result in comparable reactions by others, leaving the state no better off and perhaps worse off. The result is a world in which

status quo states predominate and revisionist states are rare. Defensive realists see a world less conflict-ridden than offensive realists.

Problems

Realism is criticized for leaving too much out. A pristine realism that only says that balances recur cannot explain most foreign policies of most states most of the time. Moreover, the theory is static and cannot explain change over time. Important transformations of recent centuries, such as the rise of nationalism, the industrial revolution, the rise of ideological politics, the spread of democracy, the revolutions in communication, transportation, and warfare, realists judge irrelevant to international politics, which they treat as unchanged as long as anarchy continues to characterize international politics. Realists deem these factors to matter only to the extent that they affect the relative power of states (whose alteration is the only source of change in international relations) and are viewed as exogenous shocks. The only transformation that some realists accept as affecting world politics is the nuclear revolution, which they consider to undercut fundamentally the importance of relative power in a classical military sense.

The theory is also vague and imprecise. It is not clear what factors enter into a calculation of the balance of power, nor how balance is ascertained. It is difficult to test assertions of the theory when there can be wide disagreement over whether a particular distribution of power is balanced or not. Scholars dispute whether stability during the Cold War derived from US military superiority, a balance of power between the US and USSR, or the existence of nuclear weapons. Scholars disagree whether past wars occurred as balance or imbalance was emerging.

More important, the theory is indeterminate. It cannot predict which particular distribution of power will emerge, only that balance will. Nor can it predict the process by which balance is restored. US containment of the Soviet Union during the Cold War can be explained as the working of the balance of power, but so can the US roll back of German and Japanese power during World War II. A US decision simply to contain German and Japanese power in the 1940s would have been as consistent with realism as the actual US decision to wage war and undo the consequences of German and Japanese aggression. The theory cannot explain when war is used to restore the balance of power and when containment restores the balance.

The theory makes precise predictions only when the constraints of the international system are presumed to be tight. Although the theory holds that it is great powers that structure global politics, the international system is most constraining of small powers and least constraining of large ones. Hence, the theory is typically indeterminate regarding the behavior of the great powers, which are presumed to matter most for international politics.

Formal studies have shown that realist premises are consistent with international cooperation, the construction of international organizations, and even the emergence of international norms. These works challenge the deductive logic of realism, arguing that the premises are insufficient to lead to realist conclusions.

Realists have had some difficulty in recent years in explaining significant international developments, as, for example, the disjuncture between military and economic power. Realists argue that economic power is invariably translated into military power relatively quickly. Yet the global disjuncture between the two has been sustained for an extended period of time. During the later stages of the Cold War, the world remained militarily bipolar, dominated by the might of the United States and the Soviet Union. Yet economically the world was multipolar, with Germany (and the EU more broadly) and Japan as significant economic powers that did not translate their economic prowess into military strength. Since the end of the Cold War, the world has been militarily unipolar (US defense spending being greater than the combined spending of the next 15 powers for much of the period) and yet the global economy was distinctly multipolar. Such sustained disjunctures between the distribution of economic and military power is problematic for realism.

As noted earlier, most realists assumed that the unipolarity of the post-Cold War world would be a short-lived phenomenon, that balancing behavior would react to imperious US power. Yet multipolarity has not emerged and most of the other rich and powerful states in the system remain aligned with the US. Some have argued that opposition to US policy by its allies constitutes a new form of soft balancing behavior, thus both conforming to realist expectations and yet constituting a new and distinct phenomenon not adequately conceptualized in realist thought.

Realists also have problems explaining the emergence of a zone of peace in central and western Europe. War is now unthinkable between states that have fought many wars over centuries. Despite remaining sovereign and autonomous, the states of Europe are no longer engaged in a security competition, and their peaceful relationships transcend the mere temporary cooperation envisaged by realism.

Modifications and Varieties of Realism

Realist thought continues to develop, in part to deal with such anomalies. One variant now posits that it is the perception of power rather than the actual distribution of power that matters. Another decouples changes in the distribution of power from the perception of threat, and holds that states respond to threats and not just shifts in power.

Some see realism as characterizing particular eras rather than international politics generally. Eras in which territorial acquisition brings greater rewards than does commercial exchange are ones to which the logic of realism is more applicable. In contrast, eras in which territorial expansion provides little wealth and great cost and in which commercial exchange is the basis for wealth and power are eras in which a realist logic is less applicable. Eras in which the nature of warfare gives the offense an edge are ones in which a realist logic is more likely to prevail, eras in which defensive weapons are superior are more stable and peaceful and not characterized by security competitions.

Realism has a core point with which no international relations scholars will argue: the international system consists of states that are sovereign and independent and there is no power

to enforce norms or law and that therefore power is a central consideration in analyzing international politics. No scholar denies the importance of states, power, and interests. Scholars of all stripes give this central core of realism its due, but then depart from other elements. The resulting desire both to amend realism and to appropriate it for important modifications has resulted in a variety of realisms. Although liberalism (and liberal institutionalism) have been proffered as conceptual alternatives, there are those suggesting a hybrid of democratic realism or liberal realism. Similarly, constructivism, critical theory, and cultural perspectives have been proffered as alternatives to realism, and here too amalgams have been proposed with the labels cultural realism, critical realism, and constructivist realism. Finally, realism is seen as quintessentially immoral, a cynical view of international life that makes war and military necessity an ethical virtue. Yet, here too, some have proposed arguments they have dubbed ethical realism and moral realism.

These varieties of realism (which many realists would deny as realist arguments) attest to the continuing centrality of power and interests in any discussion of foreign policy and international politics. Yet the resulting transmogrifications have raised the question, "is anyone still a realist?" (Legro and Moravcsik, 1999).

Realism has a core strength: its emphasis on power and interest and an unregulated international system. Yet its most pristine formulation is rejected by many, if not most, scholars who nevertheless articulate their positions relative to a core realist argument. Realism is akin to Greenwich Mean Time: more live outside than inside that time zone, but everyone measures themselves by their distance from it.

Recidivism

William D Bales, Kaleena J Burkes, Samuel JA Scaggs, and Catie L Clark, College of Criminology and Criminal Justice, The Florida State University, Tallahassee, FL, USA

© 2015 Elsevier Ltd. All rights reserved.

Abstract

With our correctional facilities suffering from overcrowding, recidivism research has become of extreme importance to policy makers and social scientists. The purpose of this article is to view recidivism from the perspective of unaccounted for populations. Typically, research that studies recidivism looks at certain outcomes (reimprisonment, rearrest, and reconviction) for offenders released from prison. However, the authors suggest that within the population of individuals able to recidivate, failing to include jail and community correction populations leaves out a large portion of the picture. Additionally, the authors discuss risk assessment tools as a means of predicting recidivism among supervised and incarcerated populations.

Sociologists, and particularly criminologists, are often concerned with the behaviors of individuals in society that fall outside of the established social norms. The study of deviance and offending is a vast field, enduring over several centuries and encompassing many disciplines. The nature of crime and offending itself is frequently discussed and hypothesized in the form of a plurality: once individuals begin to engage in crime, it is typically expected that they will continue to engage in criminal acts. The question for many theorists is not why some individuals engage in crime, but why some do not, or, alternatively, why some individuals ultimately desist from offending, while others persist. In this sense, the study of crime is also the study of recidivism.

Recidivism is commonly defined as the continuation of offending following official sanctioning by the criminal justice system (Beck, 2001; Blumstein and Larson, 1971; Maltz, 2001; Webb et al., 1976). Individuals who have been arrested, convicted, incarcerated, and/or placed on a form of community supervision who then continue to engage in illegal behaviors that result in a new arrest, conviction, period of incarceration in jail or prison, term of community supervision, and/or modification of a current term of incarceration or community supervision are said to have recidivated or reoffended. Recidivism is partly a continuation of illegal behaviors and partly the recognition and sanctioning of said illegal behaviors by the criminal justice system. One of the key roles of criminal justice practitioners and policy makers is to reduce recidivism. Actuarial risk assessment tools, which are used at multiple points in the criminal justice system, are used to determine the likelihood that an individual with a particular criminal history and miscellaneous characteristics will commit another criminal act. In a sense, these practitioners and policy makers are in the business of curtailing multiple forms of recidivism at multiple stages in the criminal justice process.

Despite the need to assess risk for reoffending in a variety of ways, the criminological literature has primarily focused on the recidivism of persons released from incarceration and has conceptualized recidivism as rearrest, reconviction, and reimprisonment. By only focusing on a limited population (released inmates) and limited measures of recidivism (rearrest, reconviction, and reimprisonment), only a small part of the recidivism picture is being captured. Ultimately, the prison population is a relatively small part of the criminal justice system compared to individuals incarcerated in local jails or placed on a variety of types of supervision in the community. Discounting the importance that the community corrections and jail populations play in contributing to the overall recidivism rate of offenders in the United States is excluding the majority of the reoffending population. These frequently overlooked and understudied populations, as well as the accuracy of the extant literature in capturing the true nature of recidivism, are focused on in this discussion of recidivism. An understanding of these other recidivism measures permits a better knowledge base about potential contributors and responses to multiple forms of recidivism.

To this end, the authors first describe the types of measures that are generally classified as recidivism as well as community- and jail-based sanctions that are not commonly included. Second, they summarize the correctional context to illustrate the abundance of people being sanctioned to community-based alternatives to incarceration and local jails. Third, they further contend that including nontraditional community-based measures of recidivism would further strengthen the validity of commonly used risk assessment tools.

Probation, Parole, and Jail Populations in the United States

The reality is that there are far more adults serving time under community supervision and in local jails than in state and federal prisons. The Bureau of Justice Statistics in 2010 indicates that 4 887 900 offenders were under some form of community supervision. In the fiscal year 2010, 2074 individuals per 100 000 (or 1 in every in 48 people) in the United States were under some form of community supervision. Based on specific breakdowns, 1721 per 100 000 (or 1 in every 58 people) were on probation in the fiscal year 2010. The overall number of adults on probation has reached 4 055 500, representing nearly 83% of the total supervised population. Alternatively, 357 per 100 000 (or 1 in every 280 people) were on parole in the fiscal year 2010, which represents a total number of 840 700 adults on parole (Glaze and Bonczar, 2011). Jails also house a substantial number of inmates

relative to prisons. According to the Bureau of Justice Statistics' annual survey of jails at midyear 2010, 748 728 inmates were confined in jails, which represents an incarceration rate of 242 per 100 000 persons. This figure is almost equivalent to the average daily population of 748 553 inmates reported by Minton (2011). In contrast, 1 612 395 (500 inmates per 100 000 residents) adults were being in held in state ($N = 1\,402\,624$) and federal ($N = 209\,771$) prisons in 2010 (Guerino et al., 2011). These figures suggest that the virtual absence of recidivism measures related to offenders under community supervision or those released from local jails results in the measurement of a relatively small portion of offenders under correctional control.

Recidivism within a Community Context

How recidivism is measured is largely contingent on the definition used for this critical outcome of sentencing and correctional strategies. While recidivism is frequently operationalized as reconviction, rearrest, and reimprisonment, there are other types of sanctions indicative of recidivism captured within the community context. These sanctions may include technical violations, new arrests, probation and parole revocation due to technical violations or new arrests, and absconding.

Technical violations are generally defined as infractions of noncriminal conditions of supervision (i.e., rule violations), while law violations are the commission of a new crime while on supervision. The process of revocation involves a modification to the individual's prior supervision conditions, which may result in an increase in supervision conditions or an outright elimination of probation or parole as well as a new sentence to jail or prison. Both the commission of a new crime and one or more technical violations may result in the revocation of probation or parole. A probation or parole term may also be revoked for drug-related violations, such as testing positive for drug use, possessing drugs, failing to report for drug testing, or failing to complete alcohol or drug treatment (Gray et al., 2001; Hughes et al., 2001).

Offenders abscond when they leave the jurisdiction in which they are being supervised without receiving prior permission. The reasons for this action are varied, but some assertions are that offenders may be fearful, distrustful of the system, or uncertain about the outcome of their situation. Despite the possibility that offenders on community supervision receive a warning, it is highly unlikely that these informal sanctions will be reliably recorded, if reported at all. Notwithstanding warnings, each type of sanction may be used to represent the act of recidivism within the community.

The Overlooked Local Jail Populations and Recidivists

Over the past several decades, in response to what has been termed 'mass incarceration,' criminological research generally, and recidivism research specifically, has been focused on offender outcomes of state and federal prisoners. Largely absent from the recidivism literature have been studies concerned with the approximately 12.9 million offenders released annually from jails in the United States (Miller and Miller, 2010). Jails are essentially the initial institutional experience that virtually every suspected or convicted offender experiences. Except for individuals suspected of very minor offenses that result in notices to appear in court, civil citations, etc., all arrestees who ultimately are convicted and sentenced to a community-based supervision sanction or to state or federal prison begin with some length of stay in a local jail facility.

The argument can be made that recidivism research devoted to determining what program interventions and correctional policies are most effective in reducing reoffending should be focused more on jail populations than any other form of correctional control for the following reasons. First, the vast majority of offenders sentenced to prison have been through local jails numerous times. Langan and Levin (2002) examined the recidivism rates of the 272 111 inmates released from the prisons systems in 15 states in the United States in 1994 and reported that 93.1% had been arrested prior to the arrest that resulted in their incarceration and averaged 8.8 prior arrests. Second, the opportunity to possibly change the criminal trajectory of individuals arrested, regardless of whether they are ultimately convicted and sentenced to some form of correctional sanction, requires some intervention at the local jail level. The dearth of research examining the correlates of offending subsequent to offenders' initial involvement in the jail system or after repeated stays in jail results in the inability to understand what programs or interventions can be used to reduce the likelihood of further immersion in the correctional system.

The Importance of Research on Jails

As the gatekeeper to the American correctional system, US jails house a significant portion of the total inmate population. For instance, 9% of jails house 48% of all inmates within any state correctional system (Stephen, 2001; Hughes, 2006). Each year, a flow of over 12 million individuals are admitted and released from jails and an average of 766 010 inmates are incarcerated on any given day. Currently, there are 3365 independently and locally administered jail facilities in the country, compared to 50 state prison systems (Beck, 2006). While state and federal prisons incarcerate convicted felons, US jails serve a broader function. First, jails process and house individuals awaiting arraignment, trial, conviction, and sentencing. Additionally, jails house convicted individuals whose sentence is generally less than a year. They may also hold individuals who violate their pretrial release, probation, or parole conditions. In order to alleviate overcrowding in prisons, jails also temporarily hold state and federal prisoners. Prior to their arrival to prisons or when they are transitioning between prisons, state and federal prisoners may temporarily spend time in jail facilities. Aside from the people serving time in jails, individuals are also supervised outside of jail facilities. In the United States in 2010, over 7% of individuals were under jail supervision in the community (excluding persons under probation and parole) (Minton, 2011). These community-based alternatives include weekend programs, electronic monitoring (EM), home detention, day reporting, community service, and treatment programs (Minton, 2011).

Jails present unique challenges for addressing the reentry needs of offenders. Jailed inmates' short incarceration periods along with the low service capacities of jails limits the opportunity for treatment and other services. According to Harlow (2003), only 14% of jail inmates, compared to 52% of state prisoners, participate in education programs. Another challenge is that the size, operation, resources, and populations of the 3365 independently operated jails may not be uniform, which has important implications for the supervision, management, and treatment of inmates. Finally, there is no community-based system to aid in the reentry process (Solomon et al., 2008). Nonetheless, despite the clear need to research jails as well as the problems that exist for jail reentry, there is, as mentioned previously, a surprising lack of empirical research in this area generally (Miller and Miller, 2010) and recidivism specifically.

Only recently have researchers (Miller and Miller, 2010; Osher, 2007; Osher et al., 2002; Solomon et al., 2008) considered the reentry issues, outcomes, and programmatic needs of postrelease jail inmates. Nonetheless, and consistent across various settings and offender populations are demographic factors (i.e., age, race, sex, marital status), socioeconomic characteristics, drug abuse histories, limited education histories, prior offense histories, and poor community support networks, which are well-documented predictors of recidivism (Benedict and Huff-Corzine, 1997; Benedict et al., 1998; Kubrin and Stewart, 2006; Petersilia, 1995; Ulmer, 2001). Another predictor of reentry success is whether jail inmates can find employment and secure housing upon their release. Depending on their offense, offenders may be further marginalized in both areas. As previously discussed, 6 of 10 jail inmates have not yet been convicted and are awaiting arraignment (Sabol et al., 2007). Examining this population of pretrial jail release offenders allows for a more differentiated evaluation of the predictors of reentry outcomes among a specific jail inmate population.

While the empirical literature on jail-based reentry programs remains in its infancy, available studies that have provided insights on this important area of corrections have generally outlined principles for effective intervention (Osher, 2007) and provided profiles of several currently implemented jail-based reentry programs within several states (Soloman et al., 2008). Unfortunately, few studies have evaluated in a methodologically rigorous manner the effect of life skills and substance abuse correctional programming on reducing recidivism. In a review of the literature on evidence-based correctional programs and interventions, MacKenzie (2006) concludes that life skills training programs are ineffective interventions for reducing recidivism because they focus on changing opportunities in the environment rather than the individual. In contrast, MacKenzie (2006) finds that incarceration-based drug treatment programs are effective interventions because they address the individual's criminogenic needs. However, with few exceptions (Turley et al., 2004), research has not yet specifically examined the impact of jail-based life skills and substance abuse treatment programs on both pretrial and sentenced offender outcomes upon release.

Only a few empirical studies have specifically tested for the effect of EM on jail inmates' outcomes during the pretrial stage. In one study, it was found that the use of EM, compared to the absence of EM, is associated with significantly higher rates of technical violations (Cooprider and Kerby, 1990). Another study evaluating pretrial jail release compared offenders on EM with offenders not on EM at the national ($n = 22\ 725$) and the federal district ($n = 7234$) levels (Cadigan, 1991). While there were no statistical controls in the analysis, the author concluded that EM offenders are higher risk defendants than non-EM offenders. Cadigan's outcome measures included failure to appear and felony and misdemeanor rearrest rates. The study's results indicate that failure to appear rates, felony rearrest rates, and misdemeanor rearrest rates for EM offenders are slightly higher than those for non-EM offenders at both the district and national levels. The study did not incorporate relevant control variables or report offense types. An area where EM has not been evaluated in previous studies involves offenders who must serve a period on EM after release from jail.

In summary, the evidence is clear that the dearth of recidivism research on the over 12 million individuals who exit local jails throughout the United States each year is a significant void in the criminological research literature. There have been major advancements over the recent past in the research conducted on offenders exiting state and federal prisons in the United States and our understanding of the correlates of recidivism and the relative effectiveness of various correctional strategies in these types of facilities is improving reentry outcomes. Devoting more effort and resources in the future to understanding the factors that are linked to higher rates of reoffending and reincarceration among local jail releases will advance the recidivism research agenda and provide policy makers and practitioners with invaluable information to reduce future jail admissions and populations.

Risk Assessment Tools

One of the most pragmatic methods for identifying whether someone recidivates is through risk assessment instruments. These tools are used by various correctional officers and staff to predict the likelihood of prison misconduct (Cunningham and Sorensen, 2006), violence, psychopathology (Hare, 2003; Hare et al., 1990), and recidivism upon release from prison. One issue with these instruments is that they only determine whether a range of social, psychological, cognitive, and biological factors predict more common forms of recidivism.

As a result of the ideological backlash in the 1980s and 1990s toward rehabilitative ideals and a reduction in resources allocated to probationary agencies, several correctional and community supervision agencies adopted risk management and avoidance tools to reduce the likelihood of reoffending. This new risk management system is geared toward maximizing the regulation and control of offenders as well as toward enhancing public safety. In what some scholars (Simon and Feeley, 2003) have called 'the new penology,' this approach views crime as a systemic issue that should be managed through actuarial instruments. While the initial goal was to assess the risk of individuals to reduce reoffending, risk management techniques quickly expanded into the realm of treatment services as well. Now risk assessment is one of the most common ways of statistically predicting the likelihood of

recidivating given the characteristics of the offender and the situation (Bonta, 2002).

The normal progression of classifying offenders within the community includes assessing the individual's propensity to engage in violent or criminal behavior, identifying the appropriate interventions given their personal characteristics, and selecting suitable supervision and treatment approaches (Lowenkamp et al., 2006). Although early subjective clinical diagnoses were most frequently implemented to classify offenders, recent empirical research suggests that objective actuarial tools may be the more reliable and efficient options relative to clinical assessments, if administered by trained staff (Bonta et al., 1998; Grove and Meehl, 1996).

The risk–need–responsivity (RNR) model represents the foundation for several instruments that assess and match offenders with corresponding treatment or programmatic needs. The 'risk' principle argues that individual be placed within a category associated with their propensity to engage in violent or criminal behavior. For instance, an individual may be assigned to a low-, medium-, or high-risk classification. According to the 'needs' principle, a criminal justice agent will assess and report the existence and magnitude of an offender's problem behaviors. Due to important considerations pertaining to the offender's amenability to treatment, the 'responsivity' principle examines individual characteristics that may hinder or augment their success from treatment (Van Voorhis et al., 2007). The behavioral philosophy of this model mandates the receipt of rewards and punishments to optimize success. Regardless of whether the focus of the program is supervision oriented or treatment oriented, the most intensive programs should be reserved for those offenders with the highest risk classification (Hanley, 2002). This model also adopts cognitive behavioral and 'social learning' elements and relies on the reinforcement of family and peers to instill positive and prosocial attitudes (Andrews and Bonta, 1998). RNR techniques have garnered some support as an effective approach to reducing recidivism in the community.

Objective instruments predict the statistical likelihood of reoffending given information about the offender. The most effective of these instruments examine both static and dynamic factors. While static factors are those characteristics of the individual that cannot be altered (i.e., age at first offense, prior convictions), dynamic factors or criminogenic needs are variables that can change over time (i.e., drug and alcohol abuse, family and peer relationships, anger management). The latter risk factors are better able to target both positive and negative individual factors that are apt to change over time. Moreover, dynamic risk factors are referred to as criminogenic needs because they represent variables that can be targeted with treatment (Bonta, 2002). A reduction in these needs has been shown to result in lower levels of recidivism (Andrews and Bonta, 1998; Andrews et al., 1990).

As a result of this new risk management approach, a host of risk assessment tools have emerged. One of the most common risk–needs assessment tools is the Level of Service Inventory-Revised, which examines information on criminal history, education, employment, alcohol and drug use, companions, and emotional and personal state (see Andrews and Bonta, 1995). Based on the risk score produced by this 54-item scale through an officer-led interview process, offenders are assessed based on their likelihood of recidivating (Lowenkamp and Bechtel, 2007). Currently, this tool is one of the most theoretically guided assessment instruments used on offender populations (Bonta, 2002) with empirically established predictive validity (Andrews and Bonta, 1995, 1998; Gendreau et al., 2002).

Importantly, these tools are used for assessing individuals exiting prison as well as those offenders who are sanctioned within the community (since the focus in the current article is on community-based measures of recidivism, the authors do not describe those risk assessment tools that measure misconduct (as an indicator of recidivism) within prison). Given that the majority of offenders receive community-based sanctions as an alternative to prison terms, there is a clear need for offenders to be assessed upon receiving a term of supervision. One of the guidelines for implementing any risk assessment tools is achieving optimal predictive validity, which is accomplished through assessing their ability to predict criminal offending (Bonta, 2002). Assuming that these instruments are used to predict offending within the community, what would be considered the optimal measureable outcomes, rearrest, reconviction, or reimprisonment? Should the predictive validity of risk assessment tools not also include other forms of infractions such as technical violations, law violations, and probation and parole revocation? Even if the objective of correctional practitioners is to reduce all forms of infractions, it would be important to examine these other types of recidivism. Additionally, if the objective is to target specific types of infractions, risk assessment tools that measure even arguably minor community-based outcomes could be used to modify the intervention (i.e., degree or conditions of supervision). Overall, the use of recidivism measures within risk assessment tools may ultimately enhance public safety, improve treatment services, and reduce correctional expenditures.

Accurately Assessing and Predicting Recidivism: The Whole Picture

Recidivism is one of the most studied topics in the criminological literature. The failure to provide more focus and attention on local jail and community correction populations results in not accurately and comprehensively assessing the problem of recidivism and how it may be reduced through various correctional strategies. It has been reported that 729 295 inmates are released from prison and return to their communities each year (Bureau of Justice Statistics, 2009, 2010), with approximately 2000 offenders released daily. With policy makers and academics diligently trying to find ways to prevent those individuals from recidivating after their release, their work is only partially addressing the recidivism problem. Even with the proliferation of validated risk assessment tools, only a portion of the story is being told relative to all forms of recidivism.

A primary reason for understanding the causes of recidivism and determining methods of reducing recidivism is to address the crime control problem in communities. Research on recidivism has taken many avenues through the focus on the

differential treatment of minority offenders (Reisig et al., 2007), gender differences in the needs of those who return to communities (Deschenes et al., 2006; Reisig et al., 2006; Holtfreter et al., 2004), gender differences in predicting recidivism (Bonta et al., 1995), offender rehabilitation (Harm and Phillips, 2000), and employment and its effects on recidivism (Wang et al., 2010). There is an importance for these areas to be studied on jail and community corrections populations as well.

Visher and Travis (2003), in an article, titled *Transitions from Prison to Community: Understanding Individual Pathways* discuss the preprison, in-prison, immediate postprison, and postrelease integration experiences (p. 94) of offenders and how each of these experiences play an important role on the decisions made once these individuals are back in the community. The authors stress the importance of how these individual experiences are extremely valuable in determining whether or not someone will or will not recidivate. However, there is only mention of offenders who are released from prison and not those released from local jails or those under community supervision who may also recidivate. Going forward, criminological research must work to incorporate jail and community correction populations in the measurement and assessment of recidivism if the true nature of this phenomenon is to be captured. Simply relying on inmate populations will not serve this discipline in the advancement of understanding offending behaviors as it excludes the largest parts of the picture.

Conclusion

National statistics indicate that the majority of offenders are being supervised in the community, which suggests that seemingly innocuous community-based measures of recidivism are as important if not more important than more conventional forms of reoffending. The observed drop in national crime rates in the past two decades allows researchers the opportunity and a little more freedom to assess alternative forms of recidivism. Eventually, the objective is to develop risk assessment procedures to determine those factors that predict status offenses, such as absconding and receiving a technical violation, and reduce them like commonly measured forms of crime.

In relation to incorporating community-based measures of recidivism, there is also a need to study jail populations when attempting to understand the current recidivism issue. These underexamined populations, once studied, could change how we as researchers and policy makers approach recidivism. There are an extremely large number of offenders (12.9 million released from jail annually and approximately 4.9 million under community supervision) who are left out of policy-making decisions when only those offenders who were released from prison are discussed. In an attempt to create more efficient and effective policies regarding reentry and recidivism in this county, these two underexamined populations must be addressed.

Research in this area should move forward by assessing the similarities as well as differences among offenders who are released from prison, those who are released from jail, and those who are under community supervision. The trends of recidivism for jail populations and community corrections should also be studied. Until recidivism is studied in regard to these two underexamined populations, the true state of recidivism cannot be fully understood.

Abstract

Recognition memory permits the distinction of items encountered in the past from those that are novel. How exactly this is accomplished has been a source of considerable theoretical debate and the number of recognition memory investigations that have been reported in the literature is astounding. Here, the authors provide readers with a brief overview of this literature. Methods that permit investigators to provide precise quantitative descriptions of recognition memory performance are described, recognition memory models said to account for empirical findings are summarized, and a subset of factors that affect the accuracy of recognition memory responses are outlined.

Recognition memory is a ubiquitous part of a person's day-to-day experience – it permits differentiation of one's car from others that are parked nearby, identification of a middle school classmate who happens to be standing nearby in the aisle at the grocery store, and selection of correct responses on multiple-choice exams. Recognition memory impairments have been linked to particular types of brain damage and dysfunction that occur as a consequence of injury, disease, or psychiatric impairment, and recognition memory errors can have substantial real-world consequences (e.g., wrongful conviction of a crime). It is not surprising then, that recognition memory has been the subject of extensive investigation in laboratory settings and that the reported results have prompted considerable theoretical debate.

In standard recognition memory experiments, participants attempt to commit information to memory (e.g., words, pictures, and nonsense syllables) so that when a test is administered, they can distinguish studied from novel materials. On these tests, participants may be asked to identify individual items as old or new (old/new recognition), select studied items presented among novel alternatives (forced-choice recognition), identify items that were presented together during a corresponding study phase (associative recognition), or identify the context in which a particular item was initially encountered (source recognition). Participants may also be asked to rate how confident they are in the accuracy of their recognition memory responses, and these confidence ratings can be used to plot receiver operating characteristic (ROC) curves. The sections that follow provide readers with a brief introduction to signal detection theory, which can be used to evaluate recognition memory performance; an overview of competing recognition memory models; and a summary of some key findings from the recognition memory literature. Factors that affect recognition memory performance – i.e., that make recognition memory decisions increasingly accurate or error prone – take top billing in this final section.

Assessing Recognition Memory Performance: Signal Detection Theory

Participants in recognition memory experiments attempt to distinguish studied from novel materials, and signal detection theory (SDT) is frequently used to evaluate performance. SDT permits quantitative assessment of the decision-making process that is used to discriminate signal from noise across a range of domains (e.g., medical diagnosis and industrial inspection) and was originally applied by psychologists to investigations of perceptual processing (e.g., presence vs absence of an auditory stimulus; see Green and Swets, 1966). In the context of recognition memory, SDT permits investigators to determine how effectively participants discriminate studied from novel materials (i.e., sensitivity), and to assess whether or not performance has been affected by any systematic response preferences (i.e., bias) such as a disproportionate tendency to endorse items as old (studied).

According to SDT, recognition decisions are mediated by the strength (or familiarity) of memory representations associated with individual items encountered on a recognition memory test; for each item, the strength of this memory signal is compared with a response criterion set by the observer and a recognition memory decision is made. On average, old items are assumed to have greater memory strength than new items by virtue of having been studied, but the distribution of memory strength across items is not uniform (i.e., some items, studied or not, seem more familiar than others) – this is depicted graphically in Figure 1, which shows that studied and novel items form overlapping Gaussian distributions. 'Old' responses are made when signal strength exceeds the criterion set by the observer and 'new' responses are made otherwise. Where exactly the criterion happens to fall is at the discretion of the participant, but may be influenced by several factors including, but not limited to, instructions administered prior to the recognition memory test (e.g., being encouraged to guess) and the possibility of reward or punishment based on performance.

Corrected Recognition Scores

The resulting model of the decision making provides a framework that can be used to characterize correct and incorrect recognition memory responses. After a recognition test has been administered, individual test trials can be assigned to one of four distinct categories based on the actual status of the test item (i.e., studied or novel) and the corresponding behavioral response made by the observer (i.e., old or new). Studied and novel items that elicit correct responses are referred to as hits and correct rejections, respectively; studied and novel items that elicit incorrect responses are referred to as misses and false alarms (see Figure 1). Something to keep in mind is that

Figure 1 Illustration of signal detection theory. Novel and studied items form overlapping Gaussian distributions. Memory strength, which is greater for the studied item distribution, is plotted on the *x*-axis. (a) Studied items correctly endorsed as 'old' based on the response criterion are shown in blue; studied items that are incorrectly rejected as 'new' are shown in yellow. (b) Novel items correctly rejected as 'new' based on the response criterion are shown in green; novel items incorrectly endorsed as 'old' are shown in orange.

evaluation of the hit rate alone does not provide a complete picture of recognition memory performance because this measure does not take into account how often participants said *old*, in error, when novel items were presented. A participant who responds *old* to most items will have a very high hit rate, but the false alarm rate will also be high, and discriminability will be poor. Therefore, the hit rate and the false alarm rate should be considered together, and investigators typically report a corrected recognition score (e.g., the hit rate minus the false alarm rate).

Discriminability and Response Bias

Although corrected recognition scores are informative, they do not tell the full story. Imagine, for example, that an experimenter has designed a recognition memory experiment with two conditions – participants study neutral or emotionally arousing pictures, and are asked to distinguish studied from novel exemplars on a corresponding recognition memory test. After having calculated corrected recognition scores for each condition, the experimenter finds that performance is better for emotionally arousing than for neutral pictures. While this outcome is notable, it provides no insight into whether the observed difference is due to superior discrimination of emotional (vs neutral) content (i.e., a difference in sensitivity), the influence of a systematic response bias, or some combination of these factors.

To avoid potential misinterpretation of results, SDT can be used to obtain numerical estimates of sensitivity (e.g., d' – pronounced 'd prime') and bias (e.g., c). The sensitivity estimate (d') indicates how far apart the old and new item distributions are from one another (see **Figure 1**) and provides a measure of discriminability. A d' score equal to zero (i.e., no difference in mean signal strength for studied and novel item distributions) indicates that participants cannot reliably distinguish old from new items (i.e., they are essentially guessing), and larger values reflect increasingly improved discriminability. The bias estimate (c) indicates how far the decision criterion is from a neutral point where old and new responses would be made equally often. Graphically, the neutral point is the place where the studied and novel item distributions cross (see **Figure 1**). If criterion is to the right of this point (i.e., c is positive), then participants have adopted a conservative response bias and favor new responses; if criterion is to the left of this point (i.e., c is negative), then participants have adopted a liberal response bias and favor old responses. A more complete explanation of SDT, along with mathematical formulas and descriptions of computer software applications that can be used to obtain quantitative estimates of sensitivity and bias, is provided by Stanislaw and Todorov (1999; for an alternative perspective readers should consult Kroll et al., 2002).

Recognition Memory Models

Several recognition memory models have been proposed in the literature. These models provide conceptual and quantitative descriptions of the processes that support recognition memory performance on a variety of tests (e.g., item recognition and associative recognition), and many of them incorporate aspects of SDT. At the broadest level, these models can be distinguished based on whether recognition memory is said to be supported by a single underlying process (i.e., memory strength/familiarity) or by two processes (i.e., familiarity and recollection). In what follows, the authors provide readers with a brief introduction to a subset of the proposed models. For more complete treatment, including detailed discussion of the points of departure across models, and descriptions of ongoing debate about the relative merits of single- and dual-process accounts of recognition memory, the authors direct readers to several excellent reviews (Clark and Gronlund, 1996; Parks and Yonelinas, 2007; Wixted, 2007; Yonelinas, 2002).

Single-Process Models

Single-process models borrow substantially from SDT and assume that recognition memory decisions are based on the strength (familiarity) of tested items. A number of single-process models, categorized collectively as global matching models (e.g., the *search of associative memory* or SAM model and the *theory of distributed associative memory* or TODAM model) have been described in the literature. These models account for a number of empirical observations – among them, observed reductions in recognition memory performance consequent to an increase in the number of to-be-remembered materials (i.e., list-length effects), incorrect endorsements of novel items as 'old' when they resemble studied materials (i.e., prototype effects), and

influences of context reinstatement on item recognition (i.e., context effects). Context effects have been documented when participants attempt to distinguish studied from novel words. For example, results show that when individual words (e.g., shadow) are studied as pairs (e.g., shadow–ladder and clock–bottle), they are more often recognized when the pairs are reinstated (i.e., shadow–ladder) at test than when they are rearranged (i.e., shadow–bottle). Global memory models predict and account for context effects by proposing that a single, strength-based metric reflects the combined influence of memory for individual items and additional associated information (e.g., the second item in a pair). This global representation of memory characteristics underlies memory strength and guides recognition memory decisions in a process that is well described by standard SDT. The origins of each model, their effectiveness in accounting for empirical findings, and their operating characteristics are evaluated in detail by Clark and Gronlund (1996). As indicated by these authors, a model that stands the test of time must account for reported results and generate new predictions. While the global memory models have been successful on both fronts, there are also empirical findings that the models cannot explain without modification (e.g., associative recognition effects). These difficulties, along with dissociations that have been reported in neuropsychological and neuroimaging experiments, suggest that recognition memory may be best described by more than one process, and that recognition memory decisions may be based on more than just the assessment of memory strength (see Clark and Gronlund, 1996; Yonelinas, 2002 for details).

Dual-Process Models

Dual-process models propose that recognition memory decisions are based on two processes – familiarity and recollection. Familiarity permits us to identify something as having been seen in the past (e.g., I know I have seen this key before), but affords no contextual detail. Recollection permits us to recognize the item and recall additional information about the context in which it was originally encountered (e.g., this is the key that opens the shed behind the house).

Early dual-process models were proposed by Atkinson et al. (Juola et al., 1971) and by Mandler et al. (Mandler et al., 1969). According to the Atkinson model, which has since been dubbed a conditional search model, an effortful memory search (i.e., recollection) is engaged if and only if a fast-acting familiarity process fails to provide conclusive evidence about whether or not an item was studied. As in SDT, studied and novel items are assumed to form overlapping Gaussian distributions, but now participants are said to adopt a low criterion as well as a high criterion. Items with signal strength that exceeds the high criterion are endorsed as old, whereas those with signal strength less than the low criterion are rejected as new. If the memory strength of an item places it in between these two criteria, then familiarity is not diagnostic and an effortful search (i.e., recollection) guides the decision-making process (hence the designation conditional search). Like Atkinson, Mandler proposed that recognition memory is governed by two processes – a fast-acting perceptual matching process (i.e., familiarity) and a slower recall process (i.e., recollection). While the two processes were initially assumed to operate in succession (as above), the model has since been revised and it is now proposed that familiarity and recollection proceed in parallel, but that familiarity is faster and 'wins the race.' According to Mandler, familiarity is the product of a perceptual match between a stimulus and a memory representation. With repeated exposure, the perceptual representation of an item is strengthened and becomes increasingly integrated in memory; this renders the perceptual match more likely during a test phase. At the same time, an increasingly elaborate contextual network is also established. This information is used to guide the memory search process (i.e., recall) and supports recollection (cf Mandler, 1980).

Jacoby et al. (e.g., Jacoby and Dallas, 1981) have also advocated for a two-process model of recognition memory; here, however, the focus has been on factors that give rise to the subjective experiences of familiarity and recollection. According to the model, feelings of familiarity are attributable to perceptual or conceptual processing fluency that has accrued based on past experience with test materials; information that is processed more easily is endorsed as having been studied. Notably, fluency does not have to be a consequence of past experience – a high-contrast word may be processed more fluently than a low-contrast word and mistakenly endorsed as having been seen during study as a result. Familiarity is characterized as fast-acting and automatic (i.e., it does not depend upon conscious deliberation or effortful retrieval attempts), and fluent processing is said to contribute to performance whether memory is tested directly or indirectly (i.e., with or without reference to a previous study experience). Recollection, on the other hand, is characterized as effortful and said to depend upon a conscious, cognitively controlled search process. In this case, participants base recognition memory decisions on the recovery of unique contextual information that was associated with a studied item when it was originally encountered.

Estimates of the contributions of recollection and familiarity to performance can be obtained via the process dissociation procedure (Jacoby, 1991). To obtain these estimates, participants might be instructed to study two separate lists of items (lists A and B). In one test condition (i.e., the inclusion condition), participants are told to endorse studied items from either list as 'old' and to reject novel items. Under these circumstances it is assumed that familiarity and recollection both contribute to accurate recognition. In a second test condition (i.e., the exclusion condition), participants are instructed to endorse items from list A as 'old,' but to reject novel items and items from list B. Here, it is assumed that any incorrect endorsement of items from list B as 'old' is attributable to familiarity because if recollection had been successful, participants would have rejected list B items as instructed. Contributions of recollection to performance are estimated by calculating the proportion of old responses made to list B items in the inclusion and exclusion conditions, and then subtracting the exclusion score (which is assumed to reflect the influence of familiarity alone) from the inclusion score (which is assumed to reflect the influences of recollection and familiarity). When the recollection estimate has been obtained, an equation can be used to estimate the contribution of familiarity to performance. The

equations used to obtain these estimates are subject to several assumptions about the processes that are being measured and the approach is not always endorsed in the literature. For a recent review that advocates for broad applicability of the process dissociation procedure and a discussion of criticisms that have been levied against it, readers should consult Yonelinas and Jacoby (2012).

Perhaps most influential among the two process models is the dual-process signal detection (DPSD) model proposed by Yonelinas (1994). According to the model, which has been applied widely to behavioral, neuroimaging, and neuropsychological investigations (Yonelinas et al., 2010), familiarity is based on the assessment of memory strength as described by SDT and recollection is threshold based. Adopting a memory threshold to characterize the experience of recollection means that this process can fail. Some items may seem familiar, but one simply cannot recall any additional detail about the context in which they were encountered. Under these circumstances, recollection does not provide any information that can be used to distinguish old from new items, but familiarity may still be diagnostic of past experience. A common misconception in the literature has been that the use of a threshold implies that recollection is all or none – i.e., participants will either recover all of the qualitative/contextual information that was associated with a particular item during encoding or nothing. Yonelinas et al. (cf Parks and Yonelinas, 2007) have clarified this point, indicating that while recollection can indeed fail to exceed threshold, above-threshold responses simply imply that some additional information has been recovered. The amount of information that is successfully retrieved may vary from trial to trial or across participants, and strong claims have not been made about the shape taken by the distribution of recollected items.

According to the DPSD model, when recollection occurs, participants will endorse items as old and indicate high confidence in the accuracy of their recognition memory decision. Items that are not recollected will be endorsed as old when memory strength exceeds criterion, and these familiarity-based recognition responses are expected to be endorsed with a range of confidence judgments. When confidence judgments have been obtained, numerical estimates of recollection and familiarity can be calculated by plotting ROC curves and fitting the data to a quantitative model. ROC curves are generated by plotting hit rates (y-axis) against false alarm rates (x-axis) at increasingly liberal levels of recognition memory confidence. The leftmost point on an ROC curve reflects corresponding hit and false alarm rates for the highest confidence responses; subsequent points reflect cumulative hit and false alarm rates at increasingly lower levels of confidence. As described in more detail by Yonelinas et al. (2010), d′ (i.e., the degree of curve in the ROC) is used to estimate contributions of familiarity to performance, and the y-axis intercept provides an estimate of recollection. Much of the current theoretical debate about the validity of proposed recognition memory models centers on the shape of ROC curves and z-transformed ROC curves. In contrast to other dual-process models, the DPSD model can predict the shape of these distributions across a wide range of empirical investigations (see Yonelinas and Parks, 2007). The same effects are also generally well predicted by a recently proposed unequal variance signal detection model in which it is stated that memory strength reflects the combined (rather than independent) influences of familiarity and recollection (Wixted and Stretch, 2004). In contrast to standard SDT, the standard deviation of the studied item distribution is greater than the novel item distribution in this model. Discussions of the relative merits and shortcomings of each approach and points of contention about the ability of each model to fit recognition memory data are provided in companion papers by Wixted (2007) and by Parks and Yonelinas (2007).

Key Findings: Factors that Affect Recognition Memory Performance

Empirical reports indicate that recognition memory performance can be affected by a range of factors (e.g., characteristics of to-be-encoded materials, processing operations engaged during encoding, and context reinstatement). Because the recognition memory literature is substantial, an exhaustive discussion of these factors is beyond the scope of this article. In what follows, the authors endeavor to highlight some of the key empirical observations that have been reported in the recognition memory literature, highlighting a subset of the factors that can make recognition memory more accurate or increasingly error prone.

The Mirror Effect: Characteristics of To-Be-Encoded Materials Affect Recognition Memory Performance

Whether or not recognition memory decisions are correct can be affected by basic properties of the materials that are used in an experiment. Simply put, some materials are more easily recognized than others. They are more likely to be endorsed as old when they have been studied and are more often rejected as new when they are novel. The classic demonstration of this material-specific advantage is based on word recognition, and shows that words with a low normative frequency (e.g., henchman) have higher hit rates and lower false alarm rates than words with high normative frequency (e.g., handyman). This word frequency effect, which has dubbed the mirror effect by Glanzer and Adams (1985), is so robust, and so easily replicated, that it is considered a regularity of recognition memory and is frequently used in classroom demonstrations. Mirror effects have also been documented in studies that manipulate list length and encoding strength. Performance advantages in these investigations are typically documented for items that were encoded in the context of short (vs long) lists, and for items that were presented more (vs less) frequently during encoding (Cary and Reder, 2003).

There is ongoing debate about what exactly drives the reported differences in recognition memory performance for low- versus high-frequency words. According to one view, the low-frequency advantage is a consequence of differences in attentional allocation. Low-frequency words benefit from extra attention during the study phase, which makes them more distinctive and more discriminable from novel exemplars at test (Malmberg and Nelson, 2003). An alternative account,

based on dual-process models of recognition memory, attributes differences in the false alarm rate to baseline levels of memory strength. Because high-frequency words are more familiar than low-frequency words, they are more likely to be endorsed as old in error. The difference in hit rate is accounted for by the observation that low-frequency words are more likely to be recollected. As indicated by Diana and Reder (2006), the above accounts are not necessarily mutually exclusive – findings from their experiments and others indicate that the recollection-based performance advantage for low-frequency words depends upon sufficient allocation of attention to these items during encoding. Future work will undoubtedly further refine theories about the mechanistic underpinnings of the mirror effect.

Facilitative Effects of Deep Encoding on Subsequent Recognition Memory Performance

The processing operations that are engaged during encoding can also affect recognition memory outcomes. According to the levels of processing model (Craik and Lockhart, 1972), materials are better remembered when they have been processed more deeply during encoding. In the context of word learning investigations, deep processing tasks encourage participants to evaluate the meaning of each word on a to-be-remembered list (e.g., indicate whether the word refers to a living or nonliving object), whereas shallow processing tasks encourage participants to evaluate superficial features of these words (e.g., indicate whether each word appears in upper or lower case text). That depth of processing does indeed affect recognition memory performance is not subject to debate and deep processing manipulations are frequently used in recognition memory experiments to facilitate encoding. Critically, evidence suggests that the reported effects are not a consequence of spurious differences in task difficulty or processing time across encoding conditions, and that they do not depend upon the intention to commit studied materials to memory (cf Craik and Tulving, 1975). Robust effects of these encoding manipulations are evident whether participants expect a recognition memory test or not, and performance on incidental recognition memory tests that follow deep encoding is on par with, or even superior to, performance when recognition memory tests are expected (Eagle and Leiter, 1964).

Context Reinstatement Effects

Intuitively, it seems that memory should be affected by whether or not there is a match between an encoding context and the associated test context. Consistent with this intuition, robust context reinstatement effects have been documented when participants attempt to recall encoded content, but the same manipulations have yielded mixed results when recognition memory tests are administered. It is difficult to provide an overarching definition of context, but in general, context refers to factors that are peripheral or subsidiary to intentionally encoded information. The studies described below are representative examples of investigations that have examined the effects of environmental and associative context manipulations on recognition memory performance.

The classic demonstration of environmental context reinstatement on memory performance was based on an experiment conducted by Godden and Baddeley (1975). Participants in this investigation studied a word list on land or underwater, and were either tested in the same environmental context or not. In this initial investigation, memory was tested via recall rather than recognition, and performance was best when the encoding and test contexts were the same (e.g., information encoded underwater was also retrieved underwater). Surprisingly, when the same experiment was conducted using a recognition test, context reinstatement did not affect performance (Godden and Baddeley, 1980). According to the encoding specificity principle (cf Thomson and Tulving, 1970), the effectiveness of a retrieval cue (in this example, environmental context) depends critically upon whether or not that information was processed and stored with to-be-encoded content, and whether or not that information is accessed during retrieval. When these requirements are not met, any anticipated benefit of an experimental manipulation may be absent. Consistent with the encoding specificity principle, it has been proposed that the relative absence of environmental context reinstatement effects may be a consequence of the failure to integrate contextual information into the memory representation that is used to support performance (Murane et al., 1999).

While a match in environmental context may not always impact recognition memory performance, effects of associative context reinstatement have been reported consistently in the literature. In these experiments, items co-occur during encoding (e.g., word pairs, faces, and scenes), but memory for the association is not emphasized and is not necessary for accurate performance during the test phase. One example of an associative context effect was described above – individual words are better remembered when studied pairs are reinstated (vs rearranged) at test despite the fact that memory for the pairs themselves is unnecessary (see Clark and Gronlund, 1996). Similar effects have also been documented in investigations that pair faces with scene contexts. In these experiments, recognition of preexperimentally unfamiliar faces is better when they are presented with the same scenes during encoding and test than when the pairings are rearranged; as in the word recognition investigations, memory for the pairing, and in this case for the scenes themselves, was not an explicitly stated performance requirement. Remarkably, this recognition memory performance advantage is evident even when the scene is a different exemplar from the same basic category (e.g., two different kitchens; Memon and Bruce, 1983; Rainis, 2001). This outcome suggests that the influence of scene context on face recognition is not strictly perceptual, but that semantic (meaning-based) characteristics are abstracted from the picture and that this higher level representation is associated with the face in memory.

These examples illustrate what was stated above – the effects of context reinstatement on recognition memory outcomes have been mixed. While some effects are robust and reproducible, others are not. More information about the effects of context on recognition memory performance, the implications of these findings for models of recognition memory (especially the global memory models), and discussion of when and under what circumstances context effects

might be expected can be found in Smith and Vela (2001) and Murane et al. (1999).

False Recognition: Factors that Make Recognition Memory Unreliable

In this final section, the authors cite work that has identified factors that make recognition memory increasingly error prone. As described above, recognition memory errors can take one of two forms – participants may fail to recognize studied information (i.e., a miss) or they may mistakenly endorse novel information as old (i.e., false alarm). Empirical investigations have focused disproportionately on one type of memory error – false alarms – perhaps because the potential consequences of false recognition can be so grave (e.g., wrongful conviction of a crime; see Wells, 1993).

Reliable demonstrations of false memory have been reported in a number of investigations that use a variety of experimental manipulations. False recognition can be induced by providing participants with misinformation about encoded content prior to test (see Loftus, 2005 for review), by manipulating the ease with which novel materials are processed (Jacoby and Whitehouse, 1989), and by presenting novel words at test that are semantically related to words from a studied list (Roediger and McDermott, 1995). All of these findings have had a substantial impact on the memory literature and are important not only empirically, but practically. For brevity, just one of these effects, the Deese–Roediger–McDermott (or DRM) effect, is described in detail here. The DRM effect is so robust that it is commonly used as a classroom demonstration to illustrate the fallibility of memory. The reliability of the effect and the simplicity of the DRM paradigm have also made it a favorite among investigators, who have used it to identify the neural substrates of false memory and to address questions about memory in special populations (e.g., children, older adults, and brain-damaged patients).

The DRM paradigm is based on a list-learning effect that was originally reported by Deese (1959) and was subsequently revived by Roediger and McDermott (1995). Participants recruited for a DRM experiment are presented with several lists of words that reliably elicit memory for a single target word that was not studied. Six lists of 12 words, each with meaning (semantics) related to one nonstudied word would be presented. A list might contain words like 'tired,' 'bed,' and 'dream,' which are all semantic associates of the nonpresented word 'sleep.' After the word lists were presented, participants would be asked to recognize the words that were studied; related, nonstudied words were presented on the recognition test as foils. Using this approach, Roediger and McDermott found that the hit rate (i.e., correct identification of studied words) was roughly equivalent to the false alarm rate (i.e., mistaken identification of foils as studied). In other words, participants were recognizing nonstudied associates of actual list members at an alarmingly high rate. When participants were asked to indicate whether they remembered the words (i.e., recollected some detail about having studied the word) or whether they simply knew the words had been presented, 72% of the false alarms were endorsed as remembered. This response corresponds to the experience of recollection, so not only were participants endorsing semantically related foils as having been studied, they were also expressing high confidence in the accuracy of their recognition memory responses.

Why exactly participants endorse these nonstudied semantic associates as remembered was puzzling as it is impossible to recover qualitative details of a study experience, when something has not been studied. To determine what was driving the reported outcome, Norman and Schacter (1997) developed a modified version of the DRM paradigm in which they had participants justify their responses when words (studied or not) were identified as old and endorsed as remembered. Participants were asked to explicitly describe details of the corresponding study experience (e.g., to indicate what words preceded/followed the remembered word, to indicate what they were thinking about when that word was presented, and to indicate whether they remembered the word because of its strong semantic relationship to other list items). It was reported that when foils were endorsed with remember responses, the most common explanation participants gave was that they had recollected the word because it was related to others on the list. In contrast, when words that were actually studied had been endorsed as remembered, participants most often reported specific sensory or contextual associations that were related to the experience of having studied those items. The same investigators reported that older adults were more susceptible to false recognition in the context of the DRM paradigm, a result that was attributed to poorer memory monitoring processes among old versus young adults.

Summary and Conclusions

The recognition memory literature has provided a number of important insights about how exactly one distinguishes studied from novel materials, and has pointed to factors that might lead one astray. Quantitative descriptions of recognition memory performance can be obtained by using SDT to analyze recognition memory data, and a number of recognition memory models provide mathematically and conceptually precise characterizations of recognition memory findings. This article was written to provide readers with an overview of the recognition memory literature and highlights a subset of the important methodological and theoretical advances that have been made over the course of the last two or three decades. An exhaustive supplemental reading list cannot be provided here, but excellent suggestions have been made by Professor Ken Malmberg. Those who are interested in learning more about recognition memory are referred to his Web site: http://uweb.cas.usf.edu/~malmberg/Recognition%20Readings.htm.

Recognition, Politics of: Perspectives from Social Work and Sociology

Stephen A Webb, Glasgow Caledonian University, Glasgow, Scotland, UK

Abstract

In critically reviewing the literature on the politics of recognition, this article situates concerns for social justice within fundamental problems of acceptance, dignity, and worth. It outlines key contributions to contemporary discussion about recognition theory and the contours of debate within sociological thought. The article demonstrates how social work is an example that illustrates the applicability of this ethical turn to a concrete case. In doing so, it reveals the explanatory power of the redistribution/recognition interaction by connecting socioeconomic and sociocultural dimensions of injustice. The article shows how along with other public good services, reevaluating social work in light of the political applicability of recognition theory can be an integral part of strategies for a just society (Macdonald, C., Merrill, R., 2002. It Shouldn't Have to be a Trade: Recognition and Redistribution in Care Work Advocacy. Hypatia 17 (2), 67–83.).

Introduction

The politics of recognition has been described as a 'turn to ethics' (Garber et al., 2000) whereby the source of social and political conflicts is seen to be rooted in social suffering. The concept of 'social suffering' is used to refer to the lived experience of pain, damage, injury, deprivation, and loss caused by misrecognition. Harm is to be viewed from the standpoint of recognition, and its absence. Recognition theory occupies a privileged place among differing conceptions of ethical worth because it does not start from principles of justice generated by thought experiments, but from the empirical needs of human beings for recognition in the form of legal respect, social care, and distributed worth. These needs can give rise to "struggles for recognition that always take place 'within' the social framework of an inherited cultural horizon" (Honneth, 1995: p. 134).

Our social and political life, with its basic rights and liberties, is thought to be protected by laws of the modern state and yet seemingly with a blink of the eye it can be so quickly transformed into what Agamben (1995) calls naked or bare life, which strips back vital forms of life. Indeed, by decree has become common since World War I in all modern states. With this notion of bare life, the central paradox posed for any progressive politics is not only the erasure of cultural and political distinctions, but also the extreme negative differentiation or alienation produced by such erasure with regard to the worth and value of a people whose form of life has been destroyed. Mobilized by an empire that prides itself on freedom, liberty, and democracy, we have witnessed the apparatus of bare life at work in Guantanamo Bay. Recognition, its political and ethical applications, promises to act as a significant counterpoint to the zones of indistinguishability so starkly exposed by Agamben. For some, recognition offers the potential for a new paradigm of social justice where a difference-friendly world is no longer subject to the assimilation of dominant economic norms or the politics of the majority. Examples include claims for the recognition of distinctive attributes of sexual preference, minority religious practices, and gendered work (Fraser, 1997).

Situating Recognition and Its Political Application

In providing a robust definition, Brandom (2009) sets out parameters for establishing the social and political contours of recognition. Starting from the premise that recognition requires not only that someone recognized by another person or group, but that the person being recognized regards the legitimacy of the other in conferring said recognition. This approach rests on the view that recognition is authorized or conferred on a person. One of the problems in providing an adequate definition of recognition relates to questions about its responsive or generative nature (Markell, 2007). The latter model concentrates on the ways in which recognition reproduces or generates justifications for actions and identity formation. In recognizing, a process of attunement occurs involving a movement of self-adjustment to a disposition or perspective, whereby a person transforms herself in the act. A conscious performance of recognition enables understanding of the processes by which we constitute ourselves and others in a shared horizon of meaning. A good enough parent, for example, is "someone who ought to act in a certain way in virtue of being recognised as, for example, recognising someone as a rational being will generate certain duties and responsibilities for both the person being recognised and those who interact with her" (McQueen, 2011: http://www.iep.utm.edu/recog_sp/). The response model of recognition is bound to the dispositions that someone possesses and normatively articulates in a way that may be subsequently affirmed. Here, to recognize someone is to acknowledge them as they already really are (Appiah, 1994: p. 149). This means that there are justifications for why one ought to confer recognition to someone prior to the act of recognition itself. Thus, for example, we ought to recognize someone's ability to be a good parent because they possess certain dispositions, of bonding and caring.

Recognition theory is thought to be especially well suited to provide for the political analysis of relations of power and associated mechanisms of social and political resistance. "As experiences of misrecognition violate the identity of subjects, the affected are supposed to be particularly motivated to resist, that is, to engage in a 'struggle for recognition'" and as such "promise to illuminate a variety of new social movements – be it the struggles of ethnic or religious minorities, of gays and lesbians or of people with disabilities" (Mattias, 2013: p. 1). Within the sphere of human rights such struggles are supposed to produce ever more just and fulfilling relations of recognition, with the demand for equal recognition of worth as the ultimate goal.

 http://dx.doi.org/10.1016/B978-0-08-097086-8.28069-0

The history of the idea of recognition stems back to the foundational work of the German philosopher Georg Hegel. For Hegel, the struggle for recognition found through an intense and enduing tension in the master–slave relation (*Anerkennung*) was famously expressed as "Self-consciousness attains its satisfaction only in another self-consciousness" (1967: p. 173). If self-consciousness exists only when recognized as such, or better still, is satisfied with an external reflection of its own freedom in the other, it is necessarily caught up in the reciprocal movement, or dialectic, in order to be certain of itself. To illustrate the dialectic of recognition, Hegel uses the custom of the greeting as a concrete example of the reciprocity at stake. Hegel has undoubtedly influenced the contemporary understanding of recognition as a political morality more than any other philosopher.

The idea of the demands for recognition features prominently in the work of leading social theorists such as Charles Taylor, Axel Honneth, Nancy Fraser, Iris Young, and Lois McNay. Each is concerned with the centrality of issues of identity in modern society. Thus the politics of recognition agenda regards justice demands as about more than the fair distribution of material goods. Young explains, "People have or lack self-respect because of how they define themselves and how others regard them, because of how they spend their time, because of the amount of autonomy and decision making power they have in their activities, and so on. Some of these factors can be conceptualized in distributive terms, but others cannot. Self-respect is at least as much a function of culture as it is of goods" (1990: p. 27). Crucially, this perspective gained salience in highlighting that concerns for recognition are primarily attempts to compensate for an underlying loss of or a displaced sense of identity. Taylor describes this critical relation between recognition and identity as follows:

> The demand for recognition in these latter cases is given urgency by the supposed links between recognition and identity, where this latter term designates something like a person's understanding of who they are, of their fundamental defining characteristics as a human being. The thesis is that our identity is partly shaped by recognition or its absence, often by the *mis*recognition of others, and so a person or group of people can suffer real damage, real distortion, if the people or society around them mirror back to them a confining or demeaning or contemptible picture of themselves.
>
> 1994: p. 25

With Taylor's Hegelianism, we witness the possibility of the achievement of identity as accorded to each by the other. The fundamental insight that subjectivity is dialogical in nature, that it is created only through interaction with an Other permits social science to recast a model of social justice around the rich life world of everyday existence. While reproduced and manifest at level of the individual, commentators insist on the profoundly collective characteristic of identity. Indeed, it is argued that the significance given to identity in the politics of recognition lies in the strength it has with affinities people have with chosen groups (e.g., organized protest at a natural gas fracking site). Arguably, it is group affiliation and networked status that define our identities and not our individual identities. Since our identity is constituted through relations with others, our being recognized by them, feelings of value, worth, and self regard are most likely to be sustained, if we are positively recognized for who we are. Indeed, in differing ways thinkers such as Taylor, Fraser, and Honneth deploy the idea of recognition to develop accounts of the individual, which are opposed to the individualism of liberal thought and to the psychologization associated with studies of self-realization and subjectivity. The idea of recognition expresses the notion that individuality is an intersubjective phenomenon formed through concrete networked relations with others. Most theories of recognition assume that in order to sustain a concrete identity, persons fundamentally depend on the feedback of other people and of society as a whole. Accordingly, those who experience a deficit of conferred recognition i.e., people or groups who are depicted negatively or perceived as worthless by societal norms and values, will find it much harder to pursue life projects in a positive way. However, distinct forms of recognition are possible only within a certain kind of community. Unlike modern Western society in which beggars are regarded as illegal scroungers in other earlier communities, mendicant orders were honored and highly regarded because they actively refused property ownership. The mendicants were destitute through choice. However, so far there has been very little analysis of the connection between recognition and the constitutive power of networks or groups or historical comparisons on the situated nature of recognition.

Recognition or Redistribution? The Fraser–Honneth Debate

Fowler suggests the redistribution and recognition debate, originally conducted by Nancy Fraser and Axel Honneth (2003), and involving Seyla Benhabib, Jessica Benjamin, and Charles Taylor, promises to be as significant "in the 21st century as the Protestant Ethic debate or the Althusserians/Culturalists debate were in the 20th century" (2009: p. 144). A key issue in the rich exchange between Fraser and Honneth is whether we need to substantively differentiate forms of social suffering: on the one hand, the denial of recognition for certain social groups who are subjected to exploitation and prejudice; and on the other hand, the consequences of vast disparities of stratified wealth and income.

The significance of developing an integrated conception of justice in the social sciences began in 1995 with the publication of articles by Fraser and Honneth. Lovell's *(Mis)recognition, social inequality and social justice* (2007a) and Fraser and Honneth's *Redistribution or Recognition?: A Political-Philosophical Exchange* (2003) trace the recent history and show the significant contribution they have made to a debate running for over a decade. Fowler (2009) claims that while other sociologists such as Pierre Bourdieu, Marion Young, and Charles Taylor have made valuable contributions to this debate, the influence of Fraser and Honneth has been by far the most compelling. At the risk of offering a limited account of the complexities entailed in the redistribution and recognition debate, the concentration here lies with Fraser and Honneth and the way this has been taken up in the valuable collection of essays edited by Lovell (2007a).

The struggle for recognition debate rests on an essential paradox of the human condition. As human beings, we need each

other in order to become human and to sustain our lives as meaningful projects. Our identities are primarily formed by processes of intersubjective recognition, which are then sustained by relations and institutions which consolidate these forms of intersubjectivity. And yet, at the same time we threaten one another's existence. Violence, neglect, abuse, or isolation of others is a permanent feature of human history. In short, we are deeply embedded in struggles for recognition (Thompson, 2006).

Honneth grounded his 'recognition' model in Hegel's early Jenna writings. Here, the idea of a fundamental unity between people, as intersubjectivity, is framed, and one that precedes their understanding of themselves as separate beings. A core preoccupation lies with how subjects related to themselves to enhance their sense of psychological well-being as a result of how significant others reacted to them. For Honneth, there are three types of recognition which lead to ontological well-being for the individual self, namely, recognition of the subject's (1) need for love and care, (2) rights as a human being, and (3) strengths or more precisely, the contribution he or she makes to the community. He regards role taking and internal conversations about expectations of our behavior were formative processes in the recognition of the other (Houston, 2013: p. 80). However, Honneth's reconstruction of social theory consists of a combination of what is most fruitful in Foucault and Habermas. From Foucault, he not only takes the embedded nature of conflictual social life, to be understood at the institutional level, but also the ever presence of power relations at the cultural, symbolic, and microphysical level of bodies and dispositions. While from Habermas, he takes the normative preoccupations with morality and intersubjective aspects of communication to evaluate the prospects for an emancipatory project (Deranty and Renault, 2007: p. 95). Honneth deliberately avoids using the term 'a politics of recognition.' His reluctance to discuss the political and focus on the ethical is justified within his theory. As Deranty and Renault note, "The driving intuition of his model is that social progress is based on the normative expectations of individuals, which must be construed as moral claims, rather than as socio-economic interests" (2007: p. 92). The struggle for recognition thus has at its root an Aristotelian teleology in the form of an 'ethical good life.'

For Fraser, modern society is comprised of two empirically interrelated but analytically distinct orders of stratification: an economic order of distributive relations that generate inequalities of social class, and a cultural order of recognition relations – relating to gender, ethnicity, age, and sexuality – that generate inequalities of status. She argues that although analytically distinct, these orders are deeply intertwined: "Even the most material economic institutions have a constitutive, irreducible cultural dimension they are shot through with significations and norms. Conversely, even the most discursive cultural practices have a constitutive, irreducible political economic dimension, they are underpinned by material supports" (1995: p. 720). As we shall see, against identity politics, Fraser's Weberian turn endorses a 'status model' in which recognition means participation in the dominant culture without discrimination, locating both recognition and misrecognition in structural elements of the wider society, rather than in the activity of the subject itself. A stark example of such forms of misrecognition exists among the 'precariat' black American ghettos and the French *banlieue*, who Wacquant notes are "compelled to form its subjectivity out of its objectification by others" (2007: p. 73).

Honneth's main line of criticism against Fraser is her dualism and the duplication of what he regards as a tired Marxist base–superstructure dichotomy. He argues that while redistribution is essential to remedy material inequalities and injustice, it can be subsumed as a subset of the politics for recognition. In short, he aims to show that the end point of Fraser's felt injustice expressed in communities, is above all, a feature of the injustice of disrespect (Lovell, 2007b: p. 5). For Honneth, Fraser's specifically separate category of economic injustice is surplus to requirements for an adequate theory of social justice. He privileges asymmetrical forms of recognition as providing the foundation of all economic inequalities and system stratifications. In Honneth's account, to be recognized *is* to be treated justly. He also accuses Fraser of being overreliant on those recognition struggles that have been publically mobilized through new social movements. Honneth maintains that the key reference point for injustice is experiential, it is what is experienced as injustice and manifest as 'psychic suffering' that is the most significant marker of exploitation and domination. In response, Fraser argues that Honneth's reductionism is inferior to her own 'perspectival dualism' in which recognition is one crucial but limited component of social justice (2003). She insists in integrating redistribution and recognition "by treating them as irreducible dimensions of a single, overarching idea of justice, which is expressed in the norm 'parity of participation'" (Markell, 2008). This notion of 'parity of participation,' "requires social arrangements that permit all to participate as peers in social life" (Fraser, 2005: p. 73) and is key to Fraser's framework of social justice (Davies et al., 2013). Her model of parity of participation challenges the undue emphasis on identity-focused approaches to participation, whereby the "result is often to impose a single, drastically simplified group identity, which denies the complexity of people's lives, the multiplicity of their identifications, and the cross-pulls of their various affiliations" (2001: p. 24). In doing so, it reveals the ways in which asymmetries of power and cultural misrecognition manifest themselves in deliberative processes.

In summary, a politics of recognition for Fraser can address cultural needs and differences but not the deep cleavages in political economy: class-based divisions, inequalities in living standards, and material disadvantage. Honneth's model is tipped overly toward questions of cultural identity. Indeed, the prevailing preoccupation with difference and celebrations of diversity in social science rests on what Fraser regards as a perverse identity politics that have the effect of displacing redistribution as a principle against economic inequalities and reifying identity. She draws attention to significant problems associated with identity politics.

> Having begun by assuming that identity is dialogical, constructed via interaction with another subject, it ends by valorizing monologism – supposing that misrecognized people can and should construct their identity on their own. It supposes, further, that a group has the right to be understood solely in its own terms – that no one is ever justified in viewing another subject from an external perspective or in dissenting from another's self-interpretation (2005: p. 112).

Thus, for Fraser, identity politics and its concomitant celebration of difference encourages separatism and rigid group enclaves. As we have seen, recognition as a form of identity politics rests on an assumed fundamental relation of self to the Other originally developed by Hegel in his master–slave dialectic. Spanning a long line of philosophers of difference from Hegel, Lacan, Derrida, and Levinas, the feminist philosopher Judith Butler maintains "… there is no self prior to its persecution by the Other. It is that persecution that establishes the Other at the heart of the self, and establishes that 'heart' as an ethical relation of responsibility" (2000: p. 25). 'Othering' is the process that is believed to create a 'them–us' dichotomy or division between people to include those in the 'us' category and exclude those in the 'them' group because they are deemed inferior.

McNay (2007) takes issue with both Fraser and Honneth in arguing that the insights of recognition theorists are undercut by their reliance on an inadequate sociological account of power thus positing a thin political solution to deeply embedded structural problems. She is struck by the way in which debates about identity politics, and identity and recognition, has been gradually overwhelmed by concerns, which in a previous era would have been seen as psychological concerns of the self; things to do with self-discovery and self-realization. The idea of recognition relies on an account of social relations as extrapolations of a primal dyad, or face-to-face dynamic of interaction that overlooks the complex ways in which individuality is connected to abstract social structures in contemporary society. Moreover, recognition is pervasively naturalized and universalized in such a way as to foreclose anything but a narrow understanding of the reproduction of structural inequalities (2007: p. 3). McNay is insistent that liberal-based consensus recognition is only a 'temporary stabilization of power,' which always involves some kind of exclusion. Using Bourdieu's relational sociology, McNay develops an alternative account of individual agency that connects identity to structure. In focusing on issues of gender identity and agency, she opens up fertile pathways to move beyond the oppositions between material and cultural feminisms conveyed in the politics of recognition.

Recognition as a Matter of Concern for Social Work

This section critically reviews the value of politics of recognition in its potential to successfully translate to a substantive field of social intervention, namely, modern social work. Both Garrett and Houston have generously outlined the main contours and contributions of the redistribution/recognition debate, particularly those of Fraser and Honneth, as well as drawing attention to the rich implications these have for social work. Given their significant in-depth treatments any reiteration, other than to outline the broad points of convergence and disagreement, would be superficial. Therefore the coverage here will provide only a schematic overview of the debate in the treatment by Houston (on Honneth) and Garrett (on Fraser and Honneth) (see Webb, 2013).

In a number of important articles, Houston has extolled the virtues of Honneth's cultural theory of recognition, which he regards as providing an ethical framework "for self-realization through symbolic interaction and mutual recognition" (2008a: p. 13). The critical leverage of such a framework is that it has the capacity to move 'individualized' direct work in social work to one 'characterized by symbolic interaction, care, respect, and validation' leading to optimal self-realization (Houston, 2008a). Honneth recruits the theoretical aid of Maslow's hierarchy of needs to cast a progressive version of self. From the standpoint of the potential of human capabilities, society is conceived as an institutional framework that either promotes or hinders individual growth (Honneth et al., 1988). However, the main problem with Maslow's (1962) approach is that individual needs are innate, so that questions of social interaction and culture are seriously downgraded. In his critique of 'individualization' in social work, he helpfully contextualizes the ethics of recognition in the practice dimensions of: (1) social work as 'symbolic interaction,' (2) social work as 'care,' (3) social work as 'respect,' and (4) social work as 'validation' (2008b: p. 8). For Houston these four dimensions are constitutive of an ethical social work that frames the person in a rich interactive social context while embodying a normative set of moral ideals. He effectively pairs the ethical turn in social sciences with a normative moral agenda of social work intervention. Self-realization is inevitably bound up with matters of recognition that are versions of individual life politics rather than universal standards of social justice. Houston considers that Honneth's recognition model can be applied in a range of social work contexts, for example, young care leavers form a group to highlight their relative disadvantage, socially and economically; adults with a sensory impairment seek to realize better practical services from a local authority; or a group of travelers fight to preserve their distinct cultural identity and choice of lifestyle (2013: p. 85). He shows how self-directed groupwork can be captured as an empowering process targeting service users' struggles for recognition centering on their experiences of disrespect, denigration, shame, outrage, and humiliation. Houston argues that social workers must be receptive to service users advocating for public recognition of their particular needs, concerns, identities, and ways of being (2013: p. 85). Davies et al. (2013) have provided empirical support for Fraser's model of parity of participation in a study of mental health and homelessness service users. The inadequacies of rights-based and consumerist approaches to service user participation are shown to reproduce institutionalized forms of cultural value and fail to engage in actual decision-making processes.

For Garrett (2009), the formality of the model of ethical life espoused by both Honneth and Houston is synonymous with a kind of political agnosticism. In Honneth's case, the failure in his conception of subjectivity is problematic, marked as it is by an unbridgeable gulf between an individual subject conceived in psychological terms, and social action conceived in abstract, general terms. Garrett is concerned that Houston reproduces these apolitical tendencies for social work. He notes that in Houston's account "the role that the more powerful structural forces play—internal and external elites, occupying forces—in promoting division and partitioning communities: generating, bolstering, structuring relations of (mis)recognition and social difference"

(p. 13) is strangely absent. Garrett puts this down to perverse blind spot in cultural recognition politics on the hegemonic position of the modern State and the role it plays in reproducing inequalities of recognition. There are two significant contributions the State performs in structuring difference: firstly "it is responsible for the discursive promulgation of categories and labels attached to particular groups" (Garrett, 2009); secondly, across its territorial jurisdictions, it "can be regarded as a literal builder and consolidator of 'difference' which is achieved via spatial and territorial separating practices (under the guise of 'peace' walls or, more routinely, of course, in terms of the control of 'borders'" (p. 14). In part, as a vehicle of the apparatus of the State it would be important to reflect on the way that social work maintains or constructs these inequalities of recognition. It would also be instructive to identify how oppositional anti-State politics of recognition are mobilized by social work and further afield. In this respect, it is important to acknowledge the ambivalent role of social work in relation to the State; not only it is complicitous, as a functionary apparatus, but also decidedly hostile to its machinations (Parton, 2008; Webb, 2009).

Garrett reaches the conclusion that "there is a case for embedding the politics of recognition into social work education and practice: perhaps particularly, the theorization of Nancy Fraser, whose perspective, although mostly neglected in the social work literature, is preferable to the narrower approach of Honneth, which, although achieving dominance within social work's engagement with recognition, is prone to 'psychologization' and psychological determinism" (p. 13). Ironically, McNay – whom Garrett mobilizes, in defense of Fraser, to criticize Honneth's subjectivist politics of recognition – condemns Fraser for the tendency to downplay the significance of experiential and interpretative perspectives. McNay (2008) claims that "Fraser's paradigm is deprived of a perspective upon the submerged experiences of everyday life that precede any politics of recognition. The move away from a focus on subjective experience means that she cannot adequately address pre-political and hidden forms of social suffering" (p. 285). As in the case, for example, of Afghan women who set themselves on fire to escape brutal beatings from husbands and forced marriages; or the thousands of farmers in India who commit suicide because they cannot afford to pay off extortionate bank loan interest. McNay is right to elevate the significance of deeply embedded forms of subjective suffering that never make it into the rights claims of recognition politics. It is relevant to note that social workers intervening in domestic violence, child abuse, families facing poverty, progressive illness in old age, and people with severe mental health problems face this sort of distress on a daily basis. However, Garrett's general point is that in social work we are tending more and more to reinterpret problems that might have been seen to have socioeconomic causation in the past, or problems that in the past would have been interpreted as social in character. The prevailing tendency – dangerously perhaps – is now to frame these material problems as having little more than a psychological dimension to them. In this respect, going full circle back to Hegel, it is worth underlining what Williams notes "For Hegel, the struggle for recognition is primarily about sociopolitical and cultural history, not about personal psychological development" (1997: p. 386).

Conclusion

Houston and Garrett have made a significant contribution to reconceptualizing politics and justice in social work drawing on recognition theory as a source of inspiration. Taken together showing that the task of developing an integrated strategy for social justice in social work is not a job for individual theorists but rather a collective project for researchers, practitioners, and service users engaged in critical deliberation. In extrapolating from both Honneth's and Fraser's contributions, a perspective on social justice must have as its object the correspondence of two homologous structures: the ethics of recognition, concerned with cultural injustice and suffering; and the ethics of redistribution, focused on redressing economic injustice – a field of power relations that is unavoidably an arena of struggle. Fraser (2003) argues that to pose an either/or choice between the politics of redistribution and the politics of recognition is to posit a false antithesis. On the contrary, justice today requires both redistribution and recognition. Indeed, the strategies of social workers engaged in struggles for social justice depends on the position they occupy in the structure of the field of redistribution and/or recognition. These are best evaluated on the basis of the degree to which it redistributes and/or recognizes and in doing so subverts existing dominant rule within the State apparatus and its forms of neoliberal economy. Radical transformation of society toward a more just world, however, ultimately rest on factors other than calculated interests and the dependency on discrete others as its object. It rests on the emotional anticipation of what Ernst Bloch (1954) called the 'principle of hope.'

Abstract

Memories are reconstructions of past events, not perfect recordings. These reconstructions can be accurate, but may also contain errors. Since the early 1900s, researchers have investigated memory processes in the laboratory and have demonstrated that reconstructions occur regardless of whether memories are retrieved after short or long periods. Reconstructive errors in memory retrieval have been shown in memory for basic objects (e.g., words, prose, pictures) and naturalistic materials (e.g., scenes, events). The implication is that understanding how memories are recollected requires considering the complex interaction of individuals' preexisting knowledge, beliefs, experiences, and goals.

Cognitive processes are active. When we perceive and encode events in the world, we construct (rather than copy) the outside world as we comprehend the events. If perceiving is a construction, then remembering the original experience involves a reconstruction. *Reconstructive memory* refers to the idea that remembering the past requires an attempt to reconstruct the events experienced previously. These efforts are based partly on traces of past events, but also on our general knowledge, our expectations, and our assumptions about what must have happened. As such, recollections may be filled with errors when our assumptions and inferences, rather than traces of the original events, determine them. Errors – false memories – constitute the prime evidence for reconstructive processes in remembering. Several different sources of error (inferences during encoding, information we receive about an event after its occurrence, our perspective during retrieval) exist. Contrary to popular belief, memory does not work like a video recorder, faithfully capturing the past to be played back unerringly at a later time. Rather, even when our memories are accurate, we have reconstructed events from the past.

In sum, reconstructive memory refers to the idea that retrieval of memories does not occur in some completely accurate form, as a video might replay a scene, but rather that recollection of memories involves a process of trying to reconstruct past events. Although the reconstruction can be quite accurate, the processes responsible can also introduce errors during retrieval. In fact, systematic errors in memory are the primary evidence for its reconstructive nature. This article provides an overview of the evidence that remembering is reconstructive.

Background

The hypothesis that remembering should be viewed as reconstructive dates to an important book by Sir Frederic Bartlett (1932). Bartlett contrasted veridical, rote forms of memory, such as reproducing a telephone number – which he called *reproductive memory* – with reconstructive memory and argued that the latter was a more typical use of memory outside laboratory and educational circumstances. That is, we are rarely faced with the task of remembering something exactly the way it happened; more frequently, we need only to get the essence of the event right. If a friend asks, "What did Kathleen say last night?" the request is not for a literal rendering of last night's conversation, but rather for the gist of what she said.

Bartlett argued that perceiving and comprehending events do not simply happen automatically, but that every event of comprehension involves the mental construction of one's understanding of the event in the world. In cases of ambiguous or difficult events, we can struggle with an "effort after meaning" in comprehending (as when you overhear a puzzling conversation and have to retrieve some relevant context to understand it). If encoding or perceiving is a construction, then when one wants to recall the events later, the attempt requires the reconstruction of the event.

Bartlett argued that remembering is guided by schemas, or general organizing structures, which aid encoding and guide retrieval. If you see a scene at the beach and are asked to recall it later, you might recall seeing a beach umbrella even if none was present in the actual scene itself, because an umbrella is consistent with the general schema of items that belong in a beach scene. Therefore, although schemas can aid encoding and guide retrieval, they can also lead to errors.

According to the standard textbook account, certain forms of remembering are reconstructive (remembering your time in the sixth grade) whereas others are reproductive (remembering a phone number or your favorite poem). However, a large amount of research is consistent with the idea that nearly all remembering is reconstructive. In fact, reconstructive memory appears to occur even when the reconstruction is quite accurate (Gallo, 2006; Roediger and McDermott, 1995). This article considers various forms of memory as they are experimentally studied and discusses evidence for reconstructive processes at work.

Sensory and Short-Term Memory

The greatest challenge to the claim in the previous paragraph, that all remembering is reconstructive, may come from studies of sensory memory, defined as the borderline between perceiving and remembering. Many theorists have argued that perceiving is itself a constructive activity, with the fascinating phenomena of visual and auditory illusions used as evidence

 http://dx.doi.org/10.1016/B978-0-08-097086-8.51016-2

for this claim (see Hoffman, 1998; among many others). Sensory memory refers to the temporary persistence of information that has struck the senses, which lingers briefly as it is being comprehended. Visual persistence is called iconic memory and auditory persistence is labeled echoic memory. It would seem that iconic memory – essentially a fleeting afterimage of the scene from the outside world – would surely be a form of reproductive memory. Yet even in these situations errors arise, showing that the retrieval processes from this type of memory involve reconstruction. For example, in Sperling's (1967) studies of iconic memory, in which people had to report letters that they had briefly seen on a screen, a common error when people missed a letter was to report another letter that either looked like or sounded like the original letter. This type of error indicates that people may code even such simple items as single letters into visual patterns and associated sounds. When people miss a *b* in these experiments, they may substitute a *v* (which sounds like *b*) or a *p* or *d*, which share both similar appearance (a long line and a curve) and similar sound (the letters rhyme with *b*). In sum, even reports from iconic memory may show reconstructive tendencies.

Short-term and working memories last longer than sensory memories do, but people are still ordinarily accurate in retrieving information from short-term stores if no interference occurs. Does this accuracy reflect a rote, reproductive process? The answer seems to be no, because when the short-term memory system is challenged by having people operate under, for example, fast rates of presentation, errors occur. Errors are often (but not always) phonological in nature. That is, if someone tries to recall letter strings and misses a letter, similar sounding letters are confused (Conrad, 1964). In the case of words, those that share visual and phonemic (sound-based) features are confused (Crowder, 1976; Chapter 4). Therefore, even though short-term memory processes are often considered quite accurate (and they can be), recall in these situations typically occurs under conditions that make for accurate reconstructions (e.g., with short unfilled delays between study and test). Stress these systems by presenting material quickly, or by creating interference, and the characteristic error pattern indicative of a reconstructive process appears.

Long-Term Memory

By far the greatest amount of research on reconstructive memory has occurred in the domain of long-term, episodic memory. Many different kinds of experiments have been conducted and we will consider some of the main types here, which have used a wide variety of materials: word lists, pictures and scenes, sentences, prose passages, and videos. Research with all these materials reveals remembrance to be quite prone to error and filling in the gaps.

Word Lists

Roediger and McDermott (1995) developed a paradigm in which people heard lists of 15 words that were generated as associates to another word, which was not itself presented. For example, subjects heard the list "hot, snow, warm, winter, ice, wet, frigid, chilly, heat, weather, freeze, air, shiver, Arctic, frost." All these words are associated to the word 'cold,' which was the word that generated the list (all the items in it were associates to 'cold'), but 'cold' was not presented. Immediately after hearing the list, subjects were asked to recall the items and were urged to be sure that the words they recalled had been presented in the list. Despite this warning not to guess, Roediger and McDermott found that their subjects recalled missing words like 'cold' at very high levels; in fact, the probability of recalling the critical item often equaled the probability of recall of the list items. After recall of many lists, subjects received a recognition test in which they were instructed to pick out only items that had actually appeared earlier in the experiment. The test included words from the lists (winter, chilly), completely unrelated words (automobile), and the critical words such as 'cold.' Subjects examined each word and, if they judged it to be old (i.e., studied), they were asked to make a remember/know judgment. This judgment (Tulving, 1985) asks people to report if they can remember the moment of the item's occurrence in the study list (a remember judgment) or if they just know it was on the list but cannot remember its moment of occurrence (a know judgment).

The recognition results are shown in Figure 1, where it can be seen that subjects were good at distinguishing studied words from unrelated lures or distracters. However, the critical lures such as 'cold' were recognized with the same likelihood as were the words in the list, about 80% of the time. In other words, people were just as likely to recognize the related but non-studied words as they were items in the list. In addition, subjects claimed to remember the moment of occurrence (as measured by remember judgments) of the critical words (that, of course, were not actually presented) at the same level as for the words that were actually studied. In short, in this paradigm subjects were just as likely to recall, recognize, and claim to remember the occurrence of words that were never presented as words that really were presented, which provides a compelling demonstration of illusory memory. The implication is that subjects reconstruct the list using their general knowledge and insert a specific memory – they remember 'cold' as having occurred – because it fits with the general theme or schema of the list.

The previous example demonstrates how reconstructive memories can be demonstrated with associative lists, but these memories can also be shown for semantic categories, as well. A chapter by Roediger et al. (2012) discusses work by Roediger and colleagues (Meade and Roediger, 2006, 2009; Roediger and DeSoto, 2013), who had subjects study category members belonging to different semantic categories (e.g., vegetables). Subjects studied 15 members from each category that were neither the most typical members of the category (e.g., carrot, lettuce, etc.) nor atypical (e.g., 'artichoke'). They were words like 'corn,' 'spinach,' and others. On a subsequent recognition test, however, subjects were highly likely to recognize highly typical category members that were never presented (e.g., carrot). These false memories were often accompanied by extremely high confidence – subjects were extremely certain that the highly typical category members were presented, even though they never were. Like the Roediger and

Figure 1 False recognition and false remembering. Mean probability of recognizing (total bar) and remembering (cross-hatched bar) studied words and lures. Unrelated lures were rarely recognized, but critical lures were recognized and remembered at about the same levels as studied words. People remember the occurrence of the critical items at the same level as words that were actually studied. Data reproduced from Roediger, H.L., McDermott, K.B., 1995. Creating false memories: remembering words not presented in lists. Journal of Experimental Psychology: Learning, Memory, and Cognition 21, 803–814 (Experiment 2).

McDermott (1995) study, this research provides evidence that semantic knowledge and schemas guide reconstructive processes that occur during remembering.

Prose Recall

A large body of research demonstrating reconstructive processes in retrieval has been carried out in prose recall. Brewer and colleagues (Brewer, 1977; Brewer and Sampaio, 2006; Brewer et al., 2005; Sampaio and Brewer, 2009) examined pragmatic implications in retention of sentences. A pragmatic implication is made when the person reading or hearing a sentence infers something that is neither explicitly stated nor logically implied by the sentence. For example, "The karate champion hit the cinder block" implies that the block was broken. However, this is a pragmatic implication; it is perfectly possible that the block was struck but not broken. After people studied sentences of this type mixed with other sentences, they were given the first parts of the sentences as cues to recall the entire sentence. Brewer (1977) showed that in recall of sentences with pragmatic inferences, people were more likely to recall the implied verb than the verb actually used in the sentence. When reconstructing the action, they remembered the champion as breaking the cinder block, not just hitting it. This result reflects a kind of inferential momentum, with people going beyond the literal truth of a statement to infer the events that probably occurred next. Often such inferences may be correct, but they are not necessarily so. When the inference is strongly made, but false, it can generate a false memory.

Sulin and Dooling (1974) also studied people's remembrance of implications as facts. In one case, they presented subjects with short paragraphs about a troubled girl and later tested for recognition both of ideas from the paragraph and of other ideas that had not been presented but that were either consistent or inconsistent with the theme of the passage. The paragraphs studied by two groups of subjects were identical, with the exception of the name above the story. In one case it was Helen Keller and in the other case it was Carol Harris. One item on the recognition test asked subjects if the following sentence had appeared in the narrative: "She was deaf, dumb, and blind." Students who had read the story about Helen Keller frequently made the error of saying that this sentence had appeared in the passage, whereas those reading about Carol Harris almost never made this error. In trying to reconstruct whether the sentence may have been in the story, the knowledge about Helen Keller caused subjects to fill in what "must have been" in the story and led subjects erroneously to conclude that the sentence was there.

Sometimes people remember the sentences that were in a prose passage no better than sentences they have never read before, so long as the new sentences are consistent with the material that was actually presented. Bransford and Franks (1971) gave subjects short sentences such as "The rock rolled down the hill" or "The rock crushed the hut." There were four simple ideas like this that, when put together, would make up the complex sentence: "The rock rolled down the hill and crushed the tiny hut." The experimenters gave their subjects various sentences to build up the complex idea unit. They later tested subjects by asking them to pick out sentences they had actually studied from among other sentences. Two types of distractor sentences were used: some were consistent with the idea unit but had not been studied, whereas other sentences were unrelated to the idea unit. The test sentences themselves could vary in the number of idea units present, from one to four. Subjects rated their belief that the sentences had been previously studied on a 10-point scale, from −5 (sure the sentence was new or nonstudied) to +5 (sure the sentence was old or studied).

The sentences that were not consistent with the idea units were accurately rejected as not having been studied, but the results for the other two types of items (shown in Figure 2) reveal that the more idea units embedded in the test

Figure 2 Mean recognition ratings for studied and nonstudied sentences as a function of number of propositions per sentence. Subjects could not distinguish sentences actually presented from those that had not been presented but that were consistent with the ideas. Data reproduced from Bransford, J.D., Franks, J.J., 1971. The abstraction of linguistic ideas. Cognitive Psychology 2, 331–350.

sentence, the higher the confidence rating that the sentence had been studied. Interestingly, this relation held both for sentences that had been studied and for new, nonstudied, sentences that were consistent with the overarching idea unit. Remarkably, except for sentences expressing only one idea, subjects were equally confident when recognizing the sentences that had not been presented in the study phase as when recognizing those that had been presented! Therefore, consistent with Bartlett's ideas, people seemed to retain the meaning of the sentences, but did not retain the literal wording of the sentences.

Bartlett (1932), who began this tradition of work, was interested in repeated recollection of material. He presented subjects with a Native American folktale, *The War of the Ghosts*, which he had them read twice. The story is a bit disjointed, has supernatural elements, and is rather difficult to understand. He found that subjects frequently made errors in recalling the story and that these errors increased over repeated retellings of the story. The stories got shorter, reflecting forgetting, but more importantly for present purposes, the story changed in systematic ways by subjects introducing errors that served to rationalize its bizarre elements. For example, people might have 'remembered' elements that had not been present to explain some of the unusual features in the story. Interestingly, this tendency to rationalize – to reconstruct the story more in line with the subject's own schema – seemed to grow over time and repeated retellings. Although Bartlett's original studies were rather informal, the work has been replicated under more systematic conditions (Bergman and Roediger, 1999).

Pictures and Scenes

Reconstructive memory has also been shown with common pictorial scenes (Miller and Gazzaniga, 1998; Weinstein and Shanks, 2010). Miller and Gazzaniga (1998) developed a procedure that used scenes that had once been covers of the *Saturday Evening Post* magazine. They showed people the scenes with a critical object from the scene removed. To use our earlier example, people might view a beach scene with a beach umbrella either present in the scene or absent from it. Miller and Gazzaniga found that when people were given recognition tests on objects in the scene, they were very likely to recognize the object as having been present when in fact it was not. Again, in reconstructing the scene, the object was inserted and seemed part of the memory.

The Misinformation Paradigm

One of the most popular paradigms for studying reconstructive processes in memory was developed by Elizabeth Loftus and her colleagues (Loftus et al., 1978) and is called the *misinformation paradigm*. It is modeled after the events that an eyewitness to a crime might experience. In the lab, subjects view a set of slides or video depicting an event, then later read a narrative or answer questions about the event. In Loftus et al. (1978), subjects witnessed an automobile accident that occurred at an intersection where a car failed to stop at a stop sign. In the later series of questions, subjects were asked either one of three questions: "Did the car stop at the traffic sign?" (control condition), "Did the car stop at the stop sign?" (consistent information condition), or "Did the car stop at the yield sign?" (inconsistent or misleading information condition). This question served as the experimental manipulation for a question asked at a later point in time: "What kind of sign was at the intersection, stop or yield?"

Results of this experiment are shown in Figure 3, where it can be seen that, relative to the control condition in which the question was posed in a neutral manner, wording of the question that was consistent with the original information improved recognition whereas the conflicting information reduced recognition. This last finding is the misinformation effect – incorrect information received after an event is often incorporated into one's memory for the event. This misinformation effect has been demonstrated in many experiments, although the magnitude of the effect depends on the exact nature of the test.

The general principle to arise from experiments on the misinformation effect is that memory for an event is not encapsulated in time the way the event itself is. Rather, information provided after the event can modify our memories for the event itself. Consistent information improves our later reconstruction, whereas conflicting or misleading information is harmful. When we try to reconstruct events from our past, we draw on all the information and resources at our disposal and the reported memory may include 'facts' that were not really part of the event, but incorporated into it later. Practically, if police or other people ask suggestive questions or embed erroneous information into questions asked of witnesses after the event, then the witnesses' later recollections and testimony might be tainted.

Figure 3 Probability correct (on a two-alternative forced choice recognition test) as a function of whether subjects had received information consistent with what they had previously seen, information inconsistent with what had been seen, or no specific postevent information. Misleading information after the event can reshape memory for the event. Data reproduced from Loftus, E.F., Miller, D.G., Burns, H.J., 1978. Semantic integration of verbal information into a visual memory. Journal of Experimental Psychology: Human Learning and Memory 4, 19–31 (Experiment 2).

Conclusion

This article has reviewed selectively some key evidence that permits us to draw the conclusion that remembering the past should be viewed as reconstructing it. To draw on a metaphor from Hebb (1949), we can think of the process of remembering the past as we conceive of paleontologists' reconstruction of a dinosaur from bone fragments and chips. The archeologist recovers a partial skeleton, but the finished product in a museum is shown as complete, with new bones added, old ones refinished or enhanced, and the entire skeleton reconstructed based on knowledge of what the animal probably looked like. Similarly, Hebb (1949) argued, remembering the past involves recollection of specific facts and details (the bones and bone chips) that are woven together into a complete story of the event (like the skeleton). However, the story about the event might involve considerable constructive activity on the part of the rememberer. A person's present knowledge and goals may shape and determine how he or she remembers the past. A quote from Bartlett captures the essence of this reconstructive approach:

> … the one overwhelming impression produced by this more 'realistic' type of memory experiment is that human remembering is normally exceedingly subject to error. It looks as if what is said to be reproduced is, far more generally than is commonly admitted, really a construction, serving to justify whatever impression may have been left by the original. It is this 'impression,' rarely defined as with much exactitude, which most readily persists. So long as the details which can be built up around it are such that they would give it a 'reasonable' setting, most of us are fairly content, and we are apt to think that what we have built we have literally retained. (Bartlett, 1932: pp. 175–176)

Recovery of Function: Dependency on Age

Bryan Kolb, Canadian Centre for Behavioural Neuroscience, University of Lethbridge, Lethbridge, AB, Canada

© 2015 Elsevier Ltd. All rights reserved.

Abstract

When the brain is injured there is a cascade of cellular events that can both seriously compromise the functioning of the brain and stimulate reparative processes that underlie eventual functional improvement. The likelihood and intensity of these cellular changes vary with the age of the individual. In particular, there are times during brain development, which begins *in utero* and continues well into the third decade of life, when brain injury may lead to strikingly different outcomes. These critical periods are related to the varying maturational events occurring at different stages of brain development.

Brain damage results in lost functions that do not completely return after injury. The brain is capable of compensatory change, however, thus allowing at least partial restitution of function, the extent of recovery varying with the precise developmental state of the brain at the time of injury. Thus, although some compensatory change is possible in the brain at any age the best outcome from cerebral injury occurs after damage during the period of maximal synaptogenesis, which is in the first two years of life in humans. The formation of new synapses provides a mechanism to modify the remaining cerebral circuitry, which in turn allows each neuron to increase its processing capacity. Although it is uncommon, in certain restricted cases the brain also may generate new neurons that can be integrated into the remaining brain and support functional recovery. Treatments that increase synaptogenesis or cell generation will enhance functional recovery and events that reduce synaptic formation will retard recovery.

When the brain is injured in adulthood there is a loss of function followed by a prolonged period during which there is partial recovery of some types of cognitive and motor functions. The extent of functional recovery varies with age and although injury to the infant brain can have less severe consequences than similar injury in adulthood, there are times during development when injury is especially devastating. These differences are related to the details of anatomical changes at different stages of brain development. The difference in functional outcome after injury at different ages is related to the injury-induced changes in neuronal structure, changes that are referred to as plastic changes. These plastic changes are similar to the neural and glial changes that are associated with learning in the normal brain. Various factors, such as experience, hormones, and drugs modulate these plastic changes. Even these factors cannot completely restore lost functions because there are limits to brain plasticity.

The Nature of 'Recovery' after Brain Injury

There are many ways to damage the brain (e.g., stroke, disease, trauma) and it is rare indeed for a family not to contain a member who is affected by one of them. For example, it is estimated that about 400 000 people with new head injuries are admitted to hospitals each year in the United States. Similarly, it is estimated that there are about 400 000 new cases of stroke every year in the United States and most surviving stroke victims experience significant cognitive loss. These figures do not include neurological disorders such as Parkinson's and Alzheimer's diseases, which together affect more than 1% of the population. The estimate in the United States is that about 48 million people have some sort of neurological disorder, excluding mental diseases such as schizophrenia, which are clearly a result of neural dysfunction.

The high incidence of brain injury and disease thus poses perhaps the most perplexing clinical neurological problem, which is the issue of how to repair the damaged brain. It is tempting to assume that if behavior improves after injury, then there is recovery of the original behavior. However, just because a behavior appears to recover does not mean that the lost behavior itself has returned. The problem is to determine when recovery has actually occurred. In fact, true recovery is a rare occurrence after brain injury.

We can identify at least three outcomes that could occur after brain injury. First, there may be a compensation resulting from an adaptation to the lost function. Compensation could reflect a change in strategy or it may represent a substitution of a new behavior for the lost one. For example, a person who has a deficit in moving the eyes can be expected to have difficulty in reading. This difficulty can be solved, however, by moving the head, which allows restitution of function (reading) by substitution of one behavior for another. Similarly, if, following a stroke, a person can walk only with the aid of a cane, the ability to walk has returned but the original walking ability has not returned, just an adaptation to the behavioral difficulty.

A second outcome might be partial restitution of the original behavior. This could reflect recovery from some sort of nonspecific effect of the injury, such as swelling, or it may reflect a genuine return of function. Behaviors that return over a period of months are likely to reflect a partial restitution of function. This is most clearly seen in people with significant language disturbances (i.e., aphasias) in which the severe deficits in making the movements of the tongue and mouth necessary to speak may diminish leaving the person with more subtle language disturbances, such as in finding words (anomia).

Third, there is a possibility that there could be a complete restitution of the original behavior. Although it is at least theoretically possible for lost functions to return completely in a plastic brain, careful behavioral analysis shows that this is

 http://dx.doi.org/10.1016/B978-0-08-097086-8.55048-X

rarely, if ever, the case in either adult laboratory animals or human patients. In principle, however, it ought to be possible to reorganize the brain to allow at least some functions to completely recover. This process is most likely in the developing brain and it has been documented for over 100 years; children with damage to language areas can show an almost complete recovery of lost language functions.

Age-Dependent Recovery

Broca first noticed in the late 1800s that damage to the speech zones of the left hemisphere during infancy did not interfere with the later development of language (Finger and Almli, 1988). Rasmussen and Milner (1977) later showed that the sparing of language functions was due to the shifting of the speech zones either to the opposite hemisphere or, in some circumstances, within the left hemisphere. In these later studies the critical factor was age: lesions of the left hemisphere language zones prior to 5 years of age changed the speech representation so that the affected language zone moved to the right hemisphere.

Similar lesions from the ages of about 6–12 still allowed recovery of language functions but this was accomplished by intrahemispheric reorganization (Krashen, 1973). The studies of the recovery of language functions after infant brain injury led to the idea that damage to the infant brain led to better functional outcomes than damage after similar injury in adulthood. This conclusion was supported by the studies of Margaret Kennard in the late 1930s in which she showed that unilateral motor cortex impairments are less severe after motor cortex injury if the lesion occurs in infancy rather than adulthood (Kennard, 1940). One difficulty with the studies of both Kennard and the language reorganization in children is that there are also many examples in which early brain damage results in rather severe functional loss, such as in cerebral palsy or hemiplegia resulting from unilateral cerebral injury at birth. In fact, Hebb (1949) noted that children with frontal lobe injuries in infancy showed little functional recovery in adulthood and for some behavior, such as social behavior, these children might actually have more severe deficits than adults with similar injuries.

The apparent contradiction between the recovery of language and some motor functions on the one hand, and the poor recovery of some executive, social, and other motor functions on the other hand, has been resolved by laboratory studies in which precise age at injury and the nature of the behavioral deficits have been systematically examined. A key element of these studies is that the age of the brain is measured not in relation to the birthday, but rather it is measured by its stage of anatomical development. For example, compared to humans, newborn rats are approximately equivalent to about 6-month old fetuses when they are born. Thus, if the newborn rat brain is damaged, we would anticipate functional symptoms similar to those of human infants whose brain is injured at the beginning of the third trimester. In order to compare across species we can separate the periods of brain development into five broad stages: neurogenesis, cell migration, cell differentiation, synaptogenesis, and gliogenesis (*see* Prenatal and Infant Development: Overview, Current Trends, Future Directions).

Studies on both laboratory rats and cats have shown that if the cortex is injured bilaterally during neurogenesis, when neurons are formed, there is substantial recovery and, if the injury is not too extensive, there can be virtually complete functional recovery. In contrast, however, if the cortex is injured in the first few days after birth in the rat, which is a time of neural migration and cell differentiation, the effect is functionally devastating as animals show far more severe effects of injury than would be expected even in aging animals. This poor outcome is niether a function of extent of injury, nor localized to particular cortical areas (Kolb, 1995).

Rather, there is something about the rat cortex shortly after birth that makes it especially vulnerable. For example, damage during this time may disturb the subsequent process of synapse formation or may even alter stem cell activity in some way. Once this phase of development is over, however, and brain development moves to the production of connections and glia, the brain shows a remarkable ability to compensate for injury. Rats or cats with cortical injuries during this phase show far better behavioral capacities in adulthood than animals with similar lesions at any other time. In fact, on some behavioral tests these animals show recovery that is virtually complete.

Importantly, this recovery is far more extensive in cognitive tasks, such as the learning of various spatial navigation problems, than it is on tests of species-typical or motor behavior (Bachevalier and Malkova, 2000; Kolb and Whishaw, 1989). In humans, spatial behavior appears to show less recovery than verbal behavior (Stiles, 2000), possibly because spatial behavior is supported by a more diffuse pattern of neural networks (Stiles, 2012). This behavior-specific recovery likely reflects the relative ease of reorganizing cortical circuitry in supporting different types of behavior. The neural substrates for less plastic behavior are presumably more highly specified and constrained during development than the neural substrates for more plastic behavior. It also reflects a difference in the way the brain produces cognitive processes versus basic sensory and motor processing. Thus, the most extensive recovery is associated with lesions of the frontal areas and the least extensive recovery is associated with damage to the primary sensory areas.

Adolescence can be viewed as a behavioral transitional period that is characterized by pruning of synapses throughout the cerebral cortex. Evidence is accumulating from both human clinical studies (Crowe et al., 2012) and laboratory animal studies (Nemati and Kolb, 2010) that the effects of cerebral injury vary with age in a nonlinear manner. For example, both children and laboratory rats with cortical injury in early adolescence have poorer cognitive outcomes than those with earlier or later injuries. In the rodent studies the poor outcomes are correlated with enhanced synaptic loss after injury in early adolescence relative to similar injury in late adolescence. Given that different cortical regions shed synapses at different rates, with the prefrontal cortex being the latest, it might be expected that the critical period for poorer outcome might vary across regions, with the prefrontal cortex being the latest (Nemati and Kolb, 2012). Areal studies are difficult in studies of human children because most research

is conducted on children with traumatic brain injuries, which are normally not well localized.

Mechanisms Underlying Recovery of Function

The fundamental assumption here is that recovery of function can occur only if there is some type of modification of the structure of the remaining brain. This structural change is necessary if the remaining brain cells are to be recruited in some manner to control behaviors that preinjury were controlled by the lost neurons. In principle, there are three ways that the brain could make changes that might support recovery. First, there could be changes in the organization of the remaining, intact, circuits in the brain. The general idea is that the brain could reorganize in some way to do 'more with less.' It is unlikely that a complexly integrated structure like the cerebral cortex could undergo a wholesale reorganization of cortical connectivity, but rather, recovery from cortical injury would be most likely to result from a change in the intrinsic organization of local cortical circuits in regions directly or indirectly disrupted by the cortical injury. Although it might be possible to produce significant reorganization of cortical connections in the young brain, the overwhelming evidence in experimental animals is that this is rare and it is just as likely to be associated with abnormal functioning as with recovery.

Second, there could be a generation of new circuitry (Stewart, 1991). Cerebral reorganization can be stimulated either by some sort of behavioral therapy or the application of some sort of pharmacological treatment. In either event, the stimulus could influence reparative processes in the remaining brain or could enhance the production of new circuitry. Once again, it seems most likely that the induced neuronal changes would be in the intrinsic organization of the cortex. One might predict that induced neuronal changes might be more extensive than in the case of endogenous change, in part because the treatment can act upon the whole brain rather than just on affected regions.

Third, there could be a generation of new neurons and glia to replace at least some lost cells. Stem cells that give rise to the neurons and glia of the brain remain active in the brain throughout life (*see* Cognitive Development in Infancy, Neural Mechanisms of; Cortical Development: Transplantation and Rewiring Studies; Hypnosis, Neural Basis of). It is thus possible that neurogenesis could be stimulated after injury, especially during development, and that these new neurons could replace those lost to injury or disease (Kolb et al., 2007). All three of these possibilities for cerebral plasticity do occur, but the likelihood of each type of change varies with age at injury.

Regardless of the proximal mechanism supporting recovery, all mechanisms presumably require changes in gene expression to manufacture the appropriate proteins. There is accumulating epigenetic evidence that a wide variety of experiences, including brain injury, produce regionally specific changes in gene expression (Mychasiuk et al., 2011).

Structural Correlates of Functional Recovery

When the brain is damaged, there is a loss of neurons in the injured area but, in addition, many neurons that are not directly injured lose their normal synaptic inputs. The immediate effects of this synaptic loss are (1) neuronal death, (2) atrophy of the dendritic and/or axonal fields that have lost their connections, and/or (3) subsequent reorganization of the connections. This reorganization can be inferred by using a Golgi stain to visualize the dendritic fields of the remaining neurons. Because the dendritic branches of a neuron provide the substrate for most of a cell's synapses, a decrease (or increase) in the amount of dendritic space available is correlated with a decrease (or increase) in the number of synapses.

The hippocampal formation of adult rats has provided a good model to study synaptic replacement. When input to the hippocampus is reduced by damage to the major input pathway via the entorhinal cortex, there is a massive denervation of the hippocampal formation, which can be seen in the atrophy of the dendritic fields of the hippocampal cells in the week after injury. Beginning at about 7–10 days after the injury, there is then a slow regrowth of the dendritic fields, although the pattern of regrowth is different from the original pattern. This regrowth reflects a reorganization of the circuitry and it is correlated with a partial recovery of function. The restructuring of the synaptic organization of the hippocampus occurs primarily because the remaining inputs to the hippocampus expand to occupy the regions of lost inputs.

A similar process appears to occur after restricted neocortical injury in adulthood as well, although the changes are less dramatic than in the hippocampus and there is much less functional recovery (Kolb, 1995). In contrast, however, there is extensive reorganization after cortical injury during development, and this reorganization is correlated with functional outcome. Golgi analyses of cortical neurons of rats with perinatal lesions consistently show a general atrophy of dendritic fields and a drop in spine density across the cortical mantle. In contrast, rats with cortical lesions around 10 days of age show an increase in dendritic fields and an increase in spine density relative to normal control littermates. Thus, animals with the best functional outcome show the greatest synaptic increase whereas animals with the worst functional outcome have a decrease in synapses relative to control animals.

But infant animals not only show changes in local cortical circuits but also in more distant cortical connectivity. Perhaps the most extensive studies of changes in cortical connectivity are those showing that after unilateral motor cortex lesions in infant rats or cats there is a major expansion of the ipsilateral corticospinal pathway from the undamaged hemisphere, which is correlated with a partial recovery of skilled forelimb use (Castro, 1990). These expanded connections do not reflect the growth of new pathways, however, but rather reflect the failure of superfluous pathways to die off during development. That is, in development there is normally a period during which many pathways are eliminated but after some types of brain injury these pathways are maintained (O'Leary, 1992). The presence of these abnormal pathways may support some types of functional recovery but it may also interfere with the normal functioning of remaining cortical functions. This possibility has been termed 'crowding' to reflect the idea that the normal functions of a cortical region can be crowded out by the development of abnormal connections (Teuber, 1975). Thus, there may be recovery of some types of behavior, such as motor functions, at the expense of other functions. This appears to be especially

likely if the injury occurs during the period of neuronal migration and unlikely if it occurs during the period of maximal synaptogenesis.

As noted earlier, synaptic change may also occur after injury because the brain generates new neurons. Although this is likely to be rare in the adult, it does occur during development, but the generation of these neurons varies with precise embryonic age and location of injury. If it is damaged during the time of neuronal generation, the brain can compensate by generating rather large numbers of new cells that appear to support at least partial restitution of function (Hicks et al., 1984). It is not known if this regenerative process occurs after injury to specific regions of the brain but it is likely a general phenomenon. Thus, if the brain is injured while it is still producing neurons, it appears capable of generating replacements. In contrast, if the brain is injured during neuronal migration there appears to be little generation of new neurons. If the same injury occurs during maximal glial formation, there is neuronal generation. This generation is selective, however, and occurs only if the midline telencephalon is damaged, namely the olfactory bulb or midline cortex (Kolb and Gibb, 2007). The newly generated tissue is functional and animals regain at least partial function.

Modulating Functional Recovery at Different Ages

The functional, molecular, and structural changes discussed to this point have been spontaneous after injury at different ages. It is possible, however, to influence the endogenous changes by various types of experiences. The best-understood experiences include behavioral therapies, pharmacological therapies, and cell-based therapies (Kolb et al., 2010). Behavioral therapies include both specific sensory and motor experiences as well as complex housing, the latter having a more generalized effect on both brain and behavior. Pharmacological treatments range from psychomotor stimulants (amphetamine, nicotine, methylphenidate) to drugs that stimulate axon regeneration (e.g., inosine). These treatments have largely been used in adult animals with little study of their efficacy for developmental injuries. Finally, the cell-based therapies take advantage of the presence of multipotent neural stem cells in the developing and adult forebrain (Reynolds and Weiss, 1992). The goal of these treatments is to stimulate the growth of endogenous stem cells that will migrate to the site of injury and regenerate the lost tissue.

As a general rule of thumb, therapies are most effective both when injuries are not extensive and when the spontaneous recovery has been restricted. For example, when rats have restricted cortical injuries in the first week of life there is less recovery than after similar injuries later in life but the very early injured brain is extremely responsive to a wide variety of treatments. Kolb and Gibb (2010) used tactile stimulation for two weeks after injury to facilitate recovery in adulthood after perinatal injury to prefrontal or parietal cortex. Similar treatment after injury in the second week, which normally leads to good spontaneous injury, had minimal effect on outcome that suggests that the spontaneous recovery had already exhausted the available plasticity. Cell-based therapies have been little used in development, the exception being Fibroblast Growth Factor-2 (FGF-2), a protein implicated in brain development and wound healing. FGF-2 stimulates functional improvement and synaptic changes after cortical injury in the first week of life but has much less impressive effects in adulthood (Comeau et al., 2007). Curiously, whereas FGF-2 induces synaptic change after perinatal injury, it mobilizes stem cells to generate and migrate to the site of injury in the second week of life (Monfils et al., 2008). These cells integrate into the developing circuitry and support both cognitive and motor recovery. This does not happen after FGF-2 treatment for similar adolescent or adult injury.

In sum, there is an age-dependent pattern of both spontaneous and treatment-facilitated recovery after cerebral injury. The age-dependent functional recovery is correlated with differing mechanisms at different ages.

Re-entry and Reintegration After Incarceration

Christy A Visher, University of Delaware, Newark, DE, USA

Abstract

With few exceptions, men and women who are incarcerated are eventually released. Reentry happens when incarceration ends. These individuals face daunting barriers to their successful reintegration and reconnection with society. Successful reentry requires strong family and community support networks and comprehensive services. Interventions that reflect these principles may hold the greatest promise for success.

Reentry is defined as the inevitable consequence of incarceration. With the exception of those who are sentenced to life without parole, die of natural causes or are executed, everyone placed in confinement is eventually released. Reentry is not a legal status. Indeed, not all prisoners are released to parole supervision; many are released directly into the community with no continuing obligation to observe special conditions of their release. Nor is reentry a new kind of program. Certainly, the pathways of reentry can be influenced by such factors as the prisoner's participation in drug treatment, education programs, religious organizations, or prison industries, but reentry is not a result of program participation. Reentry happens when incarceration ends. In other words, for those who are incarcerated, reentry is not an option. In this broad definition, 'reentry' is experienced by individuals sent to either jail or prison, federal or state facilities, and either as adults or juveniles. Juxtaposed against this fact is the experience of *reintegration*, or the individual's reconnection with the institutions of society, which is both a process and a goal.

Although there has been a lot of attention to the problem of prisoner reentry since 2000, the concept of prisoner reentry is not new. As early as 1970, John Irwin, author of *The Felon*, challenged scholars to tackle the complexities of the reentry phenomenon. Noting the irony that researchers and journalists had extensively examined the reentry challenges facing World War II veterans and Peace Corps returnees, he reached this conclusion:

> [T]here is little indication either from the literature or from interviews of persons involved in dealing with parolees of the existence of any awareness of the broader aspects of the reentry problem. This general blindness seems to be related to formal and informal societal conceptions of the ex-convict. (Irwin, 1970: p. 109)

When Irwin wrote these words, the prison population in the United States was 200 000. Today's intense interest in prisoner reentry is focused on an annual reentry cohort in the United States more than three times larger, and reentry is recognized as a significant societal problem around the world, not just in the United States. Internationally, high imprisonment rates compound the challenge to the criminal justice system that the current system of incarceration and reentry creates.

Unfortunately, a majority of released prisoners will reoffend. Repeated cycles of failure, a link between drug use and crime, and addiction masking mental health problems are common. The social costs associated with this phenomenon are significant for prisoners and their families – including higher penalties for repeated offenders, further detachment from prosocial networks – and government agencies, which include public safety concerns, and growing fiscal pressures. Some of these obstacles are not new; however, their relevance and impact has been amplified by mass imprisonment and more conservative policies and ideologies. In response, practitioners and scholars have reconsidered the logic and structure of the reintegration process for ex-prisoners in order to provide more effective services and interventions (Travis, 2005; Visher and Travis, 2003). A growing body of research has begun to document these reentry initiatives from various perspectives and methodologies.

In the United States, as the rapid expansion of prison populations in the 1980s and 1990s resulted in ever larger numbers of prisoners being released each year, policymakers realized that correctional costs could be reduced by helping individuals make a successful transition. Practitioners and policymakers alike have begun demanding evidence-based strategies that help prisoners succeed after release. Some of these strategies – education, job training, work release – were the focus of offender rehabilitation efforts 30 years ago. However, recent attention to the problem of prisoner reentry is not just focused on the individual offender, but takes a broader approach in conceptualizing the problem and devising solutions.

The Challenges of Reentry

Men and women returning home from prison face formidable and simultaneous challenges, including finding a job and a place to live, locating health services and substance abuse treatment, arranging transportation, and developing prosocial relationships. Aside from individual characteristics, other factors that affect the process of reintegration include an individual's family context, the community to which he or she is returning, and the larger sociolegal environment governed by existing policies and regulations.

Until recently, describing the characteristics of individuals who are exiting prison and the challenges they face was difficult. Prior to 2000, only a handful of small, qualitative studies had examined the lives of individuals released from prison. Moreover, these reentry experiences were often told through the eyes of service providers or parole officers. Our

understanding of the reentry process and the challenges faced by released prisoners has increased significantly through new data sources that rely on reentering individual's reports of their experiences (Lattimore and Visher 2009; Visher, 2007; Visher et al., 2010). Utilizing these self-report data reveals that prisoners' perspectives of the reentry experience differ in important respects from the assumptions shared by many practitioners, policymakers, and researchers. It is also likely that some commonly held views of prisoners are shaped by the experience of working with certain groups rather than with all those who return to society. For example, former prisoners who appear at shelters, soup kitchens, or community mental health clinics are likely to have different needs and characteristics than ex-prisoners who do not need shelters, donated food, or mental health treatment. In addition, former prisoners are not a homogeneous group and they do not have identical experiences in their transition from prison to the community. Length of sentence, experiences in prison, age, and family relationships all affect the reintegration process.

Despite this heterogeneity, numerous social and economic disadvantages characterize the vast majority of individuals who are released from prison, including poor educational attainment and employment histories, poor physical and mental health, and substance misuse (Visher et al., 2010). A small group of prisoners are able to further their education while incarcerated but such opportunities depend on the availability of education programs and inmate eligibility for those programs. Although prisoners typically report working before their incarceration, most have held only temporary jobs for short periods of time. It is well known that a majority of prisoners have extensive substance use histories, yet only a fraction of those who need substance abuse treatment receive it during incarceration (Petersilia, 2003, 2005). Moreover, given high rates of substance use, it is not surprising that exiting prisoners are also likely to suffer from health problems and mental illness (Greifinger et al., 2007; National Commission on Correctional Health Care, 2002). The majority of men exiting prison have a chronic physical or mental health condition, with the most common conditions including depression, asthma, hepatitis, and high blood pressure (Visher and Mallik-Kane, 2007). Prisoners with health problems may have a more difficult transition than others.

This portrait of former prisoners reveals the difficult challenges in their personal lives as they leave prison and return to the community. Not surprisingly, the self-reported needs of exiting prisoners mirror these challenges. The needs of former prisoners range from general needs such as more education to specific needs such as photo identification or a driver's license (Lattimore et al., 2010). Among men, the levels of expressed need are highest for education, job training, and employment, followed by the need for various transitional and health-related services. Almost all soon-to-be-released prisoners report needing more education, job training, and a job. Substantial proportions of exiting prisoners need basic transitional services such as housing, access to clothing and food, and transportation, including the need for a driver's license. A majority of prisoners need medical treatment, and many recognize their need for treatment of substance use and mental health issues. Exiting prisoners also recognize a need for services that will help them change their past behavior patterns as they return to the community, such as mentoring, services to help change criminal attitudes, and anger management classes (Lattimore et al., 2010).

Female prisoners express greater needs for services than men, especially needs for education, employment, and access to clothing and food. Moreover, women need more health services than men, including mental health treatment and substance use treatment. About one-third requested access to support groups for abuse victims. Not surprisingly, need for child-related services among exiting female prisoners is high with the vast majority of women with children needing some type of child-related service (Lattimore and Visher, 2009; Lindquist et al., 2009).

In the months after release from prison, men and women continue to report needs for a variety of services. Indeed, the highest risk of recidivism is in the 6 months after release (National Research Council, 2007). The greatest continued needs for both men and women are more education, financial assistance, and health care insurance. Yet, obtaining services in the community is difficult because of inadequate information on program or treatment availability and eligibility, lack of transportation, and poor coordination among service providers. Frustrated and overwhelmed, individuals returning to their communities often do not receive the services and treatment that they need. Relapse and recidivism is a common result.

Family

The role of family is important to understanding the reintegration of former prisoners, yet we know little about its precise impacts. In criminology, criminal behavior has long been tied to family attributes. Many studies have examined the impact of an individual's early family structure and experiences on criminal activity. However, the topic has been virtually ignored in studies of recidivism, although desistance research indicates that the family may be critical to explaining individual pathways after release from prison. Among the family influences that may be important are nature of family contact (e.g., frequency, antisocial, prosocial) and type of support offered, if any (i.e., emotional, financial, housing). In response to the renewed focus on reentry and reintegration, research attention is being focused on the family factors that lead to the success or failure of former prisoners.

Strong ties between prisoners and their families or close friends during incarceration appears to have a positive impact on postrelease success. The earliest efforts to understand the relationship between family ties and postprison success came from Lloyd Ohlin's efforts to develop a parole success prediction scale for the State of Illinois in the 1950s. Ohlin constructed an 'index of family interest' and compared the number of visits and number of visitors for a sample of releasees from Illinois State Prisons drawn from 1925 to 1935. Inmates who were classified as maintaining active family interest were more likely to be successful on parole, while those who were classified as loners experienced significantly lower rates of parole success (Ohlin, 1954). These findings were replicated in the 1970s and 1980s during a period of renewed attention to the study of family impact on postprison outcomes. Stronger ties

between inmates and families and close friends during incarceration lead to better postrelease outcomes. Prisoners who experience more family contact – whether through visits or mail, or via participation in programs intended to facilitate family contact – experience lower recidivism rates and greater success postrelease (see Holt and Miller, 1972; Hairston, 1988).

More recently, research has identified the kinds of assistance that released prisoners receive from supportive families that appear to affect postrelease outcomes. In 1999, researchers with the Vera Institute of Justice tracked and interviewed 49 people who were released from New York State prisons or New York City jails during the initial 30 days immediately following release. Nelson et al. (1999) found that for these former prisoners, family support played a critical role during that first 30 days. Specifically, the interviews revealed two important areas of family support: emotional support and housing assistance. Researchers found family acceptance and encouragement as well as perceived emotional support from family were both related to postrelease success. The recently released inmates who demonstrated the greatest success in employment and abstinence from drugs, and generally exhibited optimistic attitudes were "the ones that talked most about their family's acceptance of them" (Nelson et al., 1999: p. 10). In addition, those who returned to live with family were less likely to abscond from parole. In one large longitudinal study of released prisoners followed for up to a year, the majority reported that they had at least one close family member, and almost half had four or more close family members (Visher, 2007). Moreover, the majority of returning prisoners live with family members and/or intimate partners immediately after release.

In response to the consistent findings about the importance of family support, some jurisdictions have begun to develop programs for the family members of prisoners while the offender is incarcerated. These programs include components such as marital workshops, family education, and parenting skills; these programs have been shown to improve family relationships and ties as a means of preparing the prisoner for release and reintegration into both the family and the community (Shapiro and Schwartz, 2001). Given the consistent empirical evidence that maintaining and strengthening family ties positively affects postprison outcomes, a logical next-step was for practitioners to develop programs and services for families of inmates, through which healthy ties can be fostered. A few studies, primarily program evaluations, report that providing certain social services to families of recently released prisoners leads to several positive outcomes, including decreased drug use, fewer physical, mental, and emotional problems, and decreased recidivism (Couturier, 1995; Shapiro and Schwartz, 2001; Sullivan et al., 2002). Thus, strengthening the family network and maintaining supportive family contact can improve outcomes after prisoners are released.

Overall, family connections are important for successful reintegration. Returning prisoners who assume conventional roles within their families have greater success in their transition from prison: married men have more successful transitions than single men; men who reside with their wives and children upon release have more successful transitions than those who live alone or with a parent; and recently released inmates who describe their marriage as harmonious do better than those who describe their marriage as one of conflict (Gadsden, 2003; Waller, 1964).

Community

A third set of factors that influence individual transitions from prison to community are the characteristics of the environment to which the ex-prisoner returns. Overall, research estimating the impact of neighborhood factors such as socioeconomic status, racial diversity, and residential stability on individual outcomes shows that these effects are moderate and depend on individual characteristics (Iannotta and Ross, 2002). The study of crime and delinquency has a rich history of ecological research that has focused on the ways in which characteristics of communities may influence rates of crime and violence. Studies of neighborhood-level influences on individual criminal activity and recidivism show that structural features of neighborhoods such as residential stability, rates of organizational participation, and measures of informal and formal social control have either direct or mediated effects on individual criminal activity (see Sampson, 2002, 2012).

Returning prisoners are also increasingly concentrated in central cities and within them, in a relatively small number of neighborhoods that often are characterized by severe poverty, social disorganization, and high crime rates (Lynch and Sabol, 2001; Travis, 2005; Clear, 2007). It makes sense that a place of residence may affect individual behavior, especially for persons returning to a community after a period of absence. In the case of returning prisoners, a variety of neighborhood indicators and resources may affect postrelease outcomes, including housing values and availability, job availability or proximity to jobs, health care services, and substance abuse treatment (Travis, 2005). Moreover, the availability of social services facilitates a smoother reentry and diminishes repeat criminal activity (Freudenberg et al., 2008).

In addition to the structural features of an area, the *social* organization of a neighborhood, including the density of networks among residents, satisfaction with one's community, and the capacity of the community to join together around common goals, is also theoretically linked to rates of crime and disorder (see Sampson, 2002). Sampson et al. (1997) created a new measure of these elements, calling their concept neighborhood 'collective efficacy' – a sense of mutual trust and shared willingness to intervene for the common good. They showed that collective efficacy affected local crime rates independent of neighborhood characteristics such as poverty, residential stability, and immigrant concentration. Conceivably, neighborhood social processes may affect individual transitions from prison to community. Formal and informal social controls involving local social networks are likely to vary across neighborhoods, and these processes may deter or exacerbate individual propensities to commit crime.

Because of the geographical concentration of crime in urban areas, some neighborhoods have been affected in recent years by two types of population change: first, large numbers of men have been removed from these neighborhoods due to incarceration, and second, the return of these men as they are released from prison. The high rates of incarceration concentrated in these neighborhoods may actually increase crime because the removal of men from these areas destabilizes social

networks that promote informal social control among neighbors (Clear, 2007; Lynch and Sabol, 2000). The magnitude of the prisoner reentry phenomenon also profoundly affects other aspects of communities, including public health, homelessness, declines in civic participation, and lost connections among families and within communities. Other criminals may move in to replace the incarcerated residents. Residents in these areas may also suffer financial hardship, further weakening the vitality of the neighborhood.

Former prisoners returning to these neighborhoods may also increase neighborhood crime because the social network of the community and its ability to maintain order is already weakened. Former prisoners may have weak ties to residents, be excluded from neighborhood life, and experience some level of discrimination or stigma because of their ex-convict status (Clear, 2007). Social and structural features of neighborhoods also affect a variety of individual postrelease outcomes (other than criminal activity) that are critical to a successful transition from prison, including finding and holding a job, avoiding use of alcohol and illegal drugs, finding affordable housing, and receiving physical and mental health care (Visher and Farrell, 2005).

Sociolegal Environment

Government policy represents a fourth dimension influencing individual transitions from prison to community. The three dimensions discussed above – individual, family, and community contexts – all operate within an environment that is defined to a large extent by a network of interrelated sociolegal policies.

Although it might be reasonable to assume that individuals who have completed their sentences are free from conviction-related constraints, former prisoners likely experience collateral effects of both the prison experience and a criminal record that creates additional obstacles to a successful transition from prison back to the community. Collateral consequences are the additional penalties tied to a conviction that greatly impact an individual's capacity to engage politically, economically, and socially upon their reentry to society (Travis, 2005). These consequences include barriers to housing, education, and employment, felony disenfranchisement, and ineligibility for public benefits. Collateral consequences are distinct from direct consequences of convictions in that they are not factored into the calculation of punishment or sentencing, and are triggered outside the jurisdiction of the courts.

These collateral effects (sometimes called 'invisible punishments') may include exclusions from certain professions (e.g., realtor or health care), access to public benefits (e.g., student loans, public housing, or food stamps), as well as loss of parental rights (Petersilia, 2003; Hagan and Dinovitzer, 1999; Travis, 2005). In the United States, the federal welfare law imposes a lifetime ban on anyone convicted of a drug-related felony from receiving federally funded food assistance and cash assistance. Unless a state passes legislation opting out of the federal law, individuals with these convictions are permanently barred from receiving benefits even if they have completed their sentence, overcome an addiction, been gainfully employed and subsequently laid off, or earned a certificate of rehabilitation or other form of clemency. Denying persons with felony drug convictions food, clothing, and shelter makes it more difficult for them to support themselves as they leave the criminal justice system and reenter society. These realities, in conjunction with conditions imposed upon their release (e.g., employment, in-person reporting, payment of restitution, fees, and fines), and the need for state-approved identification and transportation, make the first few weeks and months after release especially difficult.

The collateral consequence of a prison sentence on an individual's employment prospects after release can be especially harsh. Conventional wisdom states that finding a job is one of the most important elements for a person to successfully transit from incarceration back into the community. In fact, individuals returning home from prison often identify employment as the most important factor that helped them stay crime free. Yet, most former prisoners face formidable barriers to employment. With the rapidly expanding use of background checks, employers are routinely, and increasing illegally, excluding all job applicants who have criminal records from consideration, no matter how minor or dated their offenses (Holzer et al., 2004; Pager, 2003). Thus ensues a vicious cycle: people with criminal records find it harder to get a job, but not having a job makes it more likely they will reoffend.

Overcoming the sociolegal barriers that former prisoners face in returning to their communities – whether it is finding a job, locating housing, or receiving public assistance – is critical to successful reintegration.

Emerging Policy Lessons

The successful reintegration of former prisoners into society is arguably one of the most important components of an effective criminal justice system. Yet, it seems clear from the available data and discourse that local, state, and federal policymakers are unhappy with the existing approach that relies heavily on the overburdened correctional system and are looking for strategies that will be more successful than those currently in place.

Many scholars agree that the last decade has been a revival of the rehabilitative ideal. The essence of the rehabilitationist ideal, during its heyday a half century ago as well as today, is that it is both desirable and possible to achieve positive behavioral change in individual criminal offenders. Thus, the new version of this correctional principle focuses less on the prisons themselves than on the process of prisoner reintegration into the community. It also is a harder edged, 'evidence-based' rehabilitationism, characterized by cost-benefit assessment, meta-analyses, offender 'accountability,' risk assessment, graduated sanctions, coerced treatment, and an overriding emphasis on public safety. Indeed, today's rehabilitationism is battle hardened from the 'nothing works' attitude of the 1980s and 1990s.

Researchers have developed an impressive body of studies that underscore the modest effectiveness of a variety of interventions. The prevailing opinion is that recidivism can be reduced by 10–20%, depending on program design and implementation integrity. The more successful programs include in-prison and jail drug treatment, especially with a community component; cognitive behavioral therapy;

vocational education and training programs; employment training and job assistance; and adult basic education (Aos et al., 2006; Lipsey and Cullen, 2007; MacKenzie, 2006; National Research Council, 2007). In particular, there is growing consensus that practices focusing on *individual-level change*, including cognitive change, education, and drug treatment, are likely to be more effective than other strategies, such as programs that increase opportunities for work, reunite families, and provide housing (Andrews and Bonta, 2006; Lattimore et al., 2012; MacKenzie, 2006).

The design of these reentry programs is of critical importance. Experts recommend that programs: (1) focus on behavioral outcomes, targeting criminogenic factors and using positive reinforcements; (2) target high risk offenders; (3) use risk assessment instruments; (4) begin treatment in prison and provide continuity in the community; and (5) provide intensive interventions for at least 6 months (Andrews and Bonta, 2006; Solomon et al., 2008). Thus, the most effective strategies focus on dynamic criminogenic factors, are skill-oriented, are based on cognitive/behavioral models, and treat multiple offender deficits simultaneously. Approaches with the largest impact on recidivism, possibly 20% or greater, are likely to require intensive supervision in the community with mandatory treatment programs tailored to individual needs. Further, exiting prisoners are at the highest risk for recidivism immediately after release and could benefit from intensive services during that period (National Research Council, 2007). Yet, service receipt is typically highest during incarceration (Lattimore and Visher, 2009) and the services available in the community are rarely adequate to meet the needs of these individuals in the high risk period after release.

Evaluations also point to what interventions do *not* work. The evidence has been very consistent in establishing that contact-driven supervision, surveillance, and enforcement of supervision conditions have a limited ability to change offender behavior or to reduce the likelihood of recidivism (Aos et al., 2006; MacKenzie, 2006). Individuals placed on parole supervision after prison are no less likely to be rearrested than individuals released with no supervision (Solomon et al., 2005). Other programs that have no impact on recidivism include boot camps, some types of sex offender treatment, electronic monitoring, and life skills education (MacKenzie, 2006).

A properly and fully implemented reentry program may generate improvements in intermediate outcomes, but the impacts on recidivism may be minimal. Other reentry experts have expressed similar views that poor implementation may explain why criminal justice interventions often fail to produce positive impacts on recidivism (Lowenkamp et al., 2006; White, 2007; Wilson and Davis, 2006). Some of the most common implementation problems include ineffective delivery of services, poor matching of individual needs to program content, and failure to incorporate established principles for effective rehabilitative programming. The timing and dosage of service delivery may also be important (Bourgon and Armstrong, 2005; National Research Council, 2007). Thus, greater reductions in recidivism from prisoner reentry programs may only be achieved through attention to implementation issues.

State responses to prisoner reentry have expanded dramatically in the last decade and are embracing promising strategies that create coalitions of community organizations to support returning prisoners (Lattimore, 2007; Visher and Travis, 2011). The emergence of new models of community-based reentry interventions that mobilize the resources of family, community, and positive networks of formerly incarcerated individuals in addition to traditional service delivery systems and criminal justice agencies, hold the best promise for even greater reductions in new crimes. The complexity of the disadvantages and the depths of the needs confronting men and women being released from prison means that the reentry 'problem' cannot be addressed with a single generic program or intervention. Reentry experts are encouraging a broader focus on comprehensive reentry *strategies*, not programs (Lattimore, 2007; Travis, 2005; Visher, 2007). Such strategies usually involve multiple levels of government, coordination of efforts across agencies, and involvement of organizations that are traditionally not part of the reentry discussion (e.g., public health department, the business community, local community colleges). According to best estimates of the research community, if we could implement effective programs for all returning prisoners with all the resources needed, we could expect recidivism reductions on the order of 15–20%; greater reductions may be possible with targeted, community-based strategies.

In sum, our knowledge about what works for successful reintegration has increased dramatically in the last decade. Refocusing the justice system around a reentry perspective represents a fundamental paradigm shift. In the next decade, improvements in strategies to ensure high rates of successful reintegration require rigorous evaluations of promising interventions that combine individual-based and community-based approaches.

Reference and Representation: Philosophical Aspects

Frank Jackson, Australian National University, Canberra, ACT, Australia

© 2015 Elsevier Ltd. All rights reserved.

Abstract

The concepts of representation and representational content are introduced. Examples of things that represent are barometers, sentences, and beliefs. They represent that things are a certain way. This means that they can be thought of as being about something or as referring to something – namely, the certain way in question. The article addresses the connections between representation and reference, accounts of content, representation in language, and mental representation, and discusses some theories of reference for names. The article concludes with discussions of language of thought versus map views of mental representation, and the debate over representation and context.

Representation: The General Notion

What is common to all cases of representation is a correspondence between various states of what does the representing and various states of what is represented. Thus, the number of tree rings represents the age of a tree by virtue of the possibility of matching different tree ring states with different ages. In this case, the correspondence is a very simple one: *n* tree rings correspond to an age of *n* years. Likewise, there is a simple correspondence between various states of gas gages and various levels of gas in the tank to which the gage is connected. But there are highly complex cases as well. Inscriptions in secure codes of credit card numbers represent those numbers, but via very complex correspondences. When there are pairwise correspondences, there is the possibility of carrying information. This is how the number of tree rings can give information about the age of a tree. But, of course, the nature of the correspondence needs to be known for this possibility to be realized.

In many cases, the relevant correspondence relation has a causal underpinning that runs from what's being represented to what does the representing. For example, the level of gas in the tank causes the reading on the gage, and the orientation of a windsock is caused by the direction of the wind. But structures can represent how things will be; a drawing may represent where a playground will be located but is, obviously, not caused by where it will be located. There is representation in the wide sense when there are nonaccidental correspondences between states of affairs. There will typically be a causal explanation of these nonaccidental correspondences, but its precise nature varies from case to case. (For more on the variety, see Dretske (1995), Chapter 1, but note that he ties representation to purpose.)

Representational Content and Reference in General

Things that represent are said to have representational content, the content being how things are being represented as being. The usual way of capturing representational content is set theoretically: content is given by a division of all the complete ways that things might be into those that accord with how things are being represented as being and those that do not. Complete ways that things might be are the ways things might be in which everything is settled one way or the other. They are often called possible worlds, with exactly one of these possible worlds being the actual world (our world). The content is then the set of possible worlds that accords with how things are being represented as being. For example, if a gas gage represents a gas tank as half-full, its being half-full is the content, and that is identified with the set of possible worlds where the tank is half-full. There are, though, considerable differences of opinion about the nature of the possible worlds appealed to in this style of account. This is an issue in metaphysics that will not be discussed here. (For an accessible discussion of the main views, see Bigelow and Pargetter (1990), Chapter 4.)

One advantage of the set-theoretic approach to content is that it allows a simple account of when things are as they are being represented to be. Things are as they are being represented to be – that is, the representation is true, correct, or accurate – if and only if the way things actually are is a member of the content (i.e., if and only if the actual world is a member of the set of possible worlds that is the content of the representation).

A second advantage is that it allows a simple account of the widest sense in which states that represent are about, or refer to, this, that, or the next thing. Suppose that a barometer reading of X represents the surrounding air pressure as Y. Intuitively, the reading is about the air pressure being Y. This can be spelled out as follows. In every possible world where the reading is correct, the air pressure is Y. States that represent, are about, or refer to what is the case in all the worlds where things are as they are being represented as being. (For more on 'aboutness' and the difference between being about an object and a property, see Dretske (1995), Chapter 1, Section 5.)

A third advantage is that it is easy to extend the account to cover the fact that often what's represented is how things are from a point of view. A photograph represents how things are from where it was taken. Its content can be thought of as a set of centered possible worlds, where each center is as things are being represented to be from where the photograph was taken. If the photograph is of a dog, each centered world has a dog in front of its center.

Mental Representation

A footprint can be thought of as representing the shape of the foot that made it. But equally, it can be thought of as representing the weight of the person who made it, the shape of the

footprint itself half an hour earlier, the location of the person who made it at the time it was made, and so on. Almost any state that represents will have many representational contents.

Among the representational structures of especial interest to humans are their brains, especially those parts of our brains that constitute our powers of mental representation. In particular, humans believe that things are thus and so, and do so by virtue of the processes in their brains that constitute their beliefs representing that things are thus and so. These processes *qua* states of brains will themselves have many contents, including, for example, that the temperature of the surrounding brain fluid is thus and so, but only one will be the content of what is believed. To suppose otherwise would make what is believed absurdly indeterminate. Therefore, a major question in the philosophy of mind is what determines, out of all the contents of the brain structures that are beliefs, the one that is the content of those beliefs.

One popular answer is the functional role the structure plays, where this is understood as the role the structure plays in mediating between inputs to subjects (typically via their sense organs), outputs understood in terms of behavioral responses, and other internal states. However, there are many different ways of fleshing out this answer. (For a survey, see Braddon-Mitchell and Jackson (2007), Chapters 3 and 5.)

Linguistic Representation and Reference

Introduction

Language is an especially powerful representational device. With it, highly detailed claims are possible concerning how things are that far outrun, in terms of detail and precision, what can be done with barometers, windsocks, or gas gages. This is why sentences are such a marvelous source of information.

There is a syntactical distinction between sentences and parts of sentences that roughly corresponds to an important semantic or representational distinction. A sentence makes a claim about how things are. This is how it gets to be true or false: it is true when the way the sentence represents things to be is the way they are, and false otherwise. (This is why the biconditional statement " 'Snow is white' is true if and only if snow is white" is self-evident. The left-hand side is true if and only if things are as 'Snow is white' represents them as being, and a good way of stating how 'Snow is white' represents things as being is to use the sentence itself.) By contrast, parts of sentences, like 'snow' and 'is white,' contribute in a systematic way to how the sentences in which they appear represent things as being, but do not themselves represent how things are. This is why they are not themselves either true or false. 'Snow' and 'is white' can, however, be thought of as referring to, respectively, snow and white things. This is because the contribution that the presence of the word 'snow' makes to the conditions under which 'Snow is white' is true, that is, to how the sentence represents things as being, is such that the sentence cannot be true unless there is some snow. Similarly, the contribution that the presence of 'is white' makes is such that the sentence cannot be true unless there are some white things.

Many recent discussions have focused on the referential properties of names, and some authors restrict the use of the term 'refer' to names. They prefer to talk of the relation between predicates (and, sometimes, common nouns) and things in terms of whether the predicates are *true of* the things or whether the things *satisfy* the predicates.

The next section considers the three main theories of reference for names.

Theories of Reference for Names

A word like 'London' is used for something taken to have certain properties. This is why it is not used for water or Paris – it is known that they do not have the right properties. On the other hand, the large city that is the capital of England does have the right properties. In short, certain properties or descriptions are associated with the word 'London,' and this guides its use. This suggests a simple theory of reference for names in general: 'N' refers to that which satisfies the descriptions associated with 'N'. If we use 'D' for those descriptions, another way of stating this theory is by saying that 'N' is short for the definite description 'the D.'

A famous advantage of the *description theory of reference* is that it can explain why certain identity sentences are informative. Everything is, trivially, self-identical. How then can it be informative to be told that Hesperus is identical to Phosphorus? The answer is that the first name is associated with being the first star seen in the evening and the second name is associated with being the last star to disappear from the night sky as morning approaches, and it is informative to be told that one thing has these two properties. (The classic source for claims of this kind is Frege (1966).)

Recent discussions in the philosophy of language have raised a number of objections to the description theory of reference. (A good account of the major objections can be found in Devitt and Sterelny (1999). The classic source is Kripke (1980).)

First, if 'N' is an abbreviation of 'the D,' it should make no sense to suppose that N might have failed to be D. But, in fact, it typically makes perfect sense. For example, the descriptions associated with 'Shakespeare' include as a major part that he was the author of certain plays. (Surprisingly little is known about William Shakespeare's life.) But it makes perfect sense to suppose that Shakespeare did not write the plays associated with his name, and we might discover that this supposition is true and that Christopher Marlowe, say, wrote them. A similar point can be made for names of natural kinds. The description associated with 'water' is something like potable, clear liquid that fills lakes and falls as rain from the sky – this is roughly what is in a dictionary. However, if on some remote planet – traditionally called 'Twin Earth' by philosophers – there is found clear potable stuff in its lakes that falls from its sky and so on but is not H_2O, it is arguable that the right thing to say would be that this stuff – XYZ, as it is often dubbed – is not water. As might be said, "It has been discovered that water is not the only clear potable liquid that fills lakes, falls from skies etc. in the universe." (The classic source for Twin Earth is Putnam (1975).)

Second, if names are abbreviated definite descriptions, we should be able to shift what they refer to by making appropriate changes to what's supposed to be the case. 'The president of the United States in 1998' refers to Bill Clinton, but had he lost to Bob Dole in 1996, it would refer to Dole and not

Clinton. But it seems that the reference of names cannot be shifted; they are, as it is said, *rigid designators*. 'Bill Clinton' always refers to the very same person.

Description theorists have proposed a number of replies to these (and other) objections. For example, they have urged that it is wrong to conflate the description that settles the reference of a name with the description(s) most famously associated with a name. Although Shakespeare is most famous for the plays, the key description that settles the reference of the name is something like "the person who is a certain kind of causal origin of the use of the term 'Shakespeare.'" The debate over whether or not Shakespeare wrote the plays is the debate over whether the person who is a certain kind of causal origin of the occurrences of the name on the covers of plays and the like did indeed write the plays. (For a catalog of replies that the description theorists might make to various objections, see Jackson (1998, 2010), Chapter 1.)

The causal theory of reference is the best-known alternative to the description theory. The fundamental idea is that 'Aristotle' in our mouths refers to the person it does because of an initial act of naming that tags that person with a name, which then got passed on from speaker to speaker as the name to use for the tagged person until it ended up in our mouths. (The classic source is Kripke (1980).) Of course, the name itself underwent various changes as it passed from Ancient Greek to Modern English. A similar account is suggested to explain why 'water' refers to H_2O. H_2O was named 'water' (in ignorance of the fact that it was H_2O that was being named), and then the word was passed on as the word to use for that which had been so named. This account explains why the clear potable stuff that fills the lakes and falls as rain from the sky on Twin Earth is not water and is not what is referred to when the word 'water' is used, by appealing to the fact that it was not the kind initially named.

An obvious question at this point is how, exactly, the causal theory differs from a description theory that gives a prominent role to a description like "was named … and subsequently used for what had been so named"? (Some of these questions are addressed in Devitt and Sterelny (1999), from a perspective sympathetic to the causal theory, and in Kroon (2009), from a perspective sympathetic to the description theory.)

Finally, there is *the direct reference theory of names*. On this view, a name like 'Aristotle' refers directly to Aristotle. The only semantic property of a name is its bearer. A question for this theory is what makes it true that 'Aristotle' refers to Aristotle and not to Plato or my dog. Typically this question is answered by appealing to the kind of account given by the causal theory. Accordingly, sometimes the direct reference theory and the causal theory are seen as two sides of a single coin: the causal theory gives an account of how come 'Aristotle' refers to Aristotle, and the direct reference theory gives an account of the meaning of 'Aristotle.' An issue for the direct reference theory is what to say about empty names. It has sometimes been speculated that Socrates never existed. 'He' was merely an expository device of Plato. Although this is almost certainly false, it makes sense to suppose that it is true. But is this possible if 'Socrates' has no meaning apart from its bearer? (For references, more discussion, and dissent from the direct reference theory, see Devitt (1996), Chapter 4 and Jackson (2010), and for a defense of the direct reference theory and discussion of the whole debate, see Soames (2002).)

Mental Representation and Linguistic Representation

How Are They Connected?

As noted in this article, our minds represent; in particular, to believe is to represent that things are thus and so. Usually, the easiest way for humans to express how they believe things are is to use a sentence. For example, the sentence 'Clinton will not be impeached' was used in February 1999 by many commentators on American politics to express what they believed. It is obvious that there is an intimate connection between mental and linguistic representation. What is controversial is the extent to which mental representation requires linguistic representation.

One view is that the phenomenon of mental representation in general, and belief in particular, is independent of language; dogs, for example, have beliefs. This view can allow that there are some beliefs one could not have without having a language. It is, for instance, hard to make sense of a creature believing that there are a prime number of apples in the bowl in front of it in the absence of that creature having mastery of a complex coding system (i.e., a language).

However, some hold that belief in general requires language, where language means something substantially more sophisticated than the kind of signaling systems that, for example, dogs have. Sometimes, this seems to be, at bottom, a verbal stipulation about the use of the term 'belief': dogs have quasi-belief, which is very like belief except that it is not expressed in a public language. But sometimes it is clear that the view is that dogs do not have anything like belief. A problem for this view is the close connection between perception and belief. Perceptual experience seems to be shot through with belief-like representational content: the experience of seeing something as moving seems to be a state that by its very nature supports believing that something is moving. The challenge for advocates of the more radical view is to reconcile their view that dogs, for example, lack beliefs with the fact that dogs have perceptual experiences that represent how things are. (For a defense of the view that belief requires language, see Davidson (1984), Chapter 11.)

Content and Logical Equivalence

It was noted in this article that the standard way of capturing representational content is in terms of possible worlds. The problem of the content of logically equivalent sentences and beliefs raises an important question for this view. Intuitively, the sentences 'X is an equilateral triangle in Euclidean space' and 'X is an equiangular triangle in Euclidean space' differ in meaning. Likewise, intuitively, the belief that X is an equilateral triangle in Euclidean space and the belief that X is an equiangular triangle in Euclidean space are different beliefs. Couldn't you have one belief without having the other? But, on standard conceptions of possible worlds, 'X is an equilateral triangle in Euclidean space' and 'X is an equiangular triangle in Euclidean space' are true in exactly the same possible worlds, because the sentences are logically equivalent. The same goes for the corresponding beliefs.

There have been, broadly speaking, three reactions to this problem. One has been to bite the bullet and insist that the contents are the same. (The most worked-out version of this

response can be found in Stalnaker (1984).) A second has been to argue that, for the purposes of capturing the content of, for example, belief and language, we need to bring concepts into the picture. To believe that X is an equilateral triangle in Euclidean space is to believe that X falls under the concept *equilateral triangle in Euclidean space*, whereas to believe that X is an equiangular triangle in Euclidean space is to believe that X falls under the concept *equiangular triangle in Euclidean space*. These are different concepts because the concept *side* differs from the concept *angle*, and we can therefore allow that the beliefs (and the sentences that express them) have different contents despite being true at the very same worlds (see Peacocke, 1983; for an overview of the issues, see Braddon-Mitchell and Jackson, 2007). A third has been to argue that we should allow that there is more than one legitimate way of thinking of content, and meaning more generally. It is a mistake to demand that we make a choice (see Lewis, 1986, Chapter 1, Section 4).

Mental Representation and the Language of Thought

The functionalist answer to how a belief gets to have the belief content that it does was described earlier in this article, and it was noted that there are many views about how to spell out the key functional roles. However, a popular answer holds that an important part of any functionalist account is the way belief and desire work together to produce behavior: roughly, subjects behave in a way such that what they desire is satisfied if what they believe is true (Stalnaker, 1984; Braddon-Mitchell and Jackson, 2007). This is the key to what determines the content of both belief and desire.

An alternative approach – the language of thought hypothesis – appeals to the idea that creatures with beliefs and desires (and contentful mental states more generally) have a language of thought. When subjects believe that snow is white, they have in their heads a sentence in *mentalese* that says that snow is white. (This approach allows that dogs may have beliefs, because it is possible to have an internal language of thought while lacking a public language in which to express them.) This approach gives functional role a place in determining the difference, for example, between belief and desire, but content is treated via a *semantics for mentalese*. Consider, for example, subjects who believe that snow is white. They have in their heads a token that stands for snow (the mentalese word for snow) and a token that stands for whiteness (the mentalese predicate for whiteness), put together in a structure that makes up the mentalese sentence *snow is white*. What makes it true that they believe rather than desire that snow is white is the functional role this structure plays: it serves more of a 'responding to the world' role and less of a 'changing the world' role. (A classic source is Fodor (1988).)

This approach raises many important issues. One is how we should spell out the crucial relation between the words of mentalese and what they stand for. What makes it true that a structure in the brain is the mentalese for snow and not water, for example? One proffered answer is some kind of causal cum informational link between brain token and what is tokened, but the details are controversial. A second issue is whether neurological investigations might refute the language of thought hypothesis. Some cognitive scientists have argued that the way the brain represents the environment is more like the way maps represent than the way sentences represent (see Braddon-Mitchell and Jackson, 2007 and for a reader-friendly discussion of how research into the brain informs views of mental representation, see Clark, 2001).

Representation and Context

Representational content is often thought of as context dependent. For example, what a gas gage represents about the level of gas in the tank depends on the nature of the connection between gage and tank. Connected in one of the more usual ways, the gage having its pointer in the far left position indicates that the tank is empty, but connected differently that pointer position might represent that the tank is full. That is to say, identical gage configurations can have very different representational contents depending on the gage's context. Or, as it is often put, representational content with respect to the amount of gas in the tank does not supervene on a petrol gage's configuration. As it is put, the content is broad, wide, or context dependent.

It is equally possible, however, to think of any given reading as saying: either the gage is connected to the tank in way W_1 and the gas level is L_1, or the gage is connected in way W_2 and the level is L_2, or …. In this way of thinking, a way that is naturally adopted when the nature of the connection between gage and tank is unknown, the content is not dependent on the nature of the connection.

In other words, and speaking more generally, there are two essentially equivalent ways of thinking of the interplay of representational content and context. In the first, it looks like this:

In C_1, S represents that P_1
…
In C_i, S represents that P_i

In the second, it looks like this:

S represents that if C_1, then P_1
…
S represents that if C_i, then P_i

In the first way of thinking, content comes out as context dependent or broad; in the second, it comes out as context independent or, as it is said, narrow.

A pressing, currently much debated question about both mental and linguistic content is whether we should think of it in the context-dependent or in the context-independent way. Or, equivalently, is what a person believes and what a person claims about how things are (e.g., when they speak and write) a broad or narrow property of them?

The traditional view is that mental and linguistic content is narrow. A principal source for this view is a hypothesis often imagined by science fiction writers. Suppose the stimuli actually impinging on subjects via their environments are duplicated exactly, say, by a computer, then the subjects will not be able to tell the difference. This is the core idea behind flight simulators and virtual reality machines. Although these devices fall short of perfectly duplicating the impacts of their target environments on their subjects, their makers take it for granted

that were perfect duplication achieved, subjects would be unable to tell whether, for example, they were really flying or in a simulator. This suggests that subjects' mental lives, including how their mental states represent things as being, supervene on their nature from the skin in (or, perhaps, from their central processors in). How their mental states represent things as being is, therefore, a narrow property of subjects: two subjects that are identical from the skin in are identical in how they take their worlds to be, desire them to be, and so on. Moreover, if the content of sentences is given by the content of the mental states they serve to express, it will follow that linguistic content is narrow.

However, many philosophers, often influenced by the Twin Earth example discussed in this article, repudiate this suggestion. Consider, runs their argument, Mary and Mary's duplicate from the skin in, Twin Mary, on Twin Earth. They both use the word 'water' for the clear, potable stuff around them, but the conditions under which what is said is true, and equally those under which what is thought is true, differ. What Mary says and thinks when she uses the sentence "There is water nearby" is true if and only if there is H_2O nearby, but what Twin Mary says and believes will be true if and only if there is XYZ nearby. Hence, runs the argument, the contents of the words and thoughts of Mary and Twin Mary differ; ergo, content is context dependent.

The issue is complicated, however, by the fact that it is plausible that there is an indexical element to the use of a great many words, including 'water.' It is plausible that the word 'water' is used in part to mean the stuff that the users of the word have come across that is typically clear, potable, and so on. If this is right, a plausible explanation of why Mary and Twin Mary refer to different stuff in thought and talk when they use the word 'water' is that they and their language communities interact with different stuff when the word 'water' is used. That is, Mary refers to the clear, potable stuff that she and her community interact with, whereas Twin Mary refers to the stuff she and her (different) community interact with, and the reason they refer differently is that the stuff they interact with is different. This means that there is a sense in which what they say and think is the same when they say and think, "There is water nearby." Each says and thinks that some of the clear, potable stuff that she herself interacts with is nearby. This does not affect the point that the truth conditions of what they say and think differ, but they differ in the same way that the truth conditions of "I am bald" differ depending on who is speaking. There is a good sense in which each person who says or thinks that he is bald says or thinks the same thing, namely, that they are one of the bald people, despite the fact that the conditions under which what they say and think is true differ. If X says and thinks it, it is true just if X is bald; if Y says and thinks it, it is true just if Y is bald. (There is a large literature on this question; see Pessin and Goldberg (1996) and Braddon-Mitchell and Jackson (2007) for discussion and references.)

Abstract

A person's reference group can be considered either as a source of normative orientation or as a group of social comparison in making a judgment, irrespective of one's group membership. The concept has mainly been applied in two theoretical traditions of research: While symbolic interactionists and social psychologists outlined the normative importance of reference groups for the development of the self, structural functionalist sociologists analyzed how material deprivation is estimated relative and with reference to other groups of comparison in the social structure. The concept has also played an important role in developing the discipline's methodology of social research.

A reference group is a group to whom one orients as a source of individual values and perspectives or with which one compares oneself in making a judgment or evaluation, irrespective of group membership. The concept designates a group of 'significant others' providing standards, expectations, and a frame of reference against which a person judges his or her own situation, and initially has been coined by Herbert H. Hyman in his social psychology of status judgment (Hyman, 1942). Hyman's distinction of a person's identificatory and judgmental group orientations has been analytically specified by Harold H. Kelley (1952) by distinguishing a normative from a comparative function of a reference group: The former indicates that whenever a group is "in a position to award recognition to the person or to withhold it," its function is that of "setting and enforcing standards" for a person motivated to be accepted by a group in showing conformity to its norms and role performance (Kelley, 1952: 412). Conversely, the concept's comparative meaning indicates the perceptual, judgmental aspect of a group's function "serving as or being a standard or comparison point against which the person can evaluate himself and others" (Kelley, 1952: 413). Although the very same reference group might serve both functions (Merton, 1957: 284), subsequent research has taken that distinction mainly as one between different types of reference groups. Turner outlined that the term's normative meaning can be regarded as synonymous for the process of role-taking, in which one adopts the group's standpoint as one's own, whereas interpreting a reference group as a point of a social comparison indicates a broader, more inclusive concept: Merely taking a reference group of others into account, and viewing it from a third-party standpoint, in order to accomplish one's purposes, estimate one's social standing, or decide whether to feel satisfied or not, does not necessarily mean to take the role of a member (Turner, 1956: 327). This enlarged meaning of the concept has been explicated by Robert Merton and Alice Kitt Rossi, particularly indicating the relevance of those structural conditions under which nonmembership groups constitute a significant frame of reference for a person (Merton and Kitt, 1950; Merton, 1957). Much research on reference group behavior has conceptually been clarified by them, in order to explain the selection of normative reference groups, and the consequences of that process in terms of social structure. In drawing such conceptual distinctions, they not only pointed to the structural sources of social comparisons for explaining people's feelings of satisfaction, legitimacy, and justice, but have also generated a distinct theory of reference group behavior. In empirical research, the concept has been applied to an array of social problems, for instance, adolescents' social conformity and deviance, college students' political attitudes and future orientation, immigrants' identity boundaries and social mobility, social scientists' communication patterns, role models' influence in public opinion formation and voting behavior, industrial workers' behavior toward trade unions, and the term's relevance for explaining the genesis and nature of mass revolutionary consciousness. Many of these studies are available in edited books, the volume of Hyman and Eleanor Singer still covering most of them, and the broad empirical use of the concept contributed to developing the methodology of social research as well (Newcomb and Hartley, 1947; Sherif and Sherif 1956; Merton and Lazarsfeld, 1950; Swanson et al., 1952; Eisenstadt, 1954; Lazarsfeld and Rosenberg, 1955; Lipset and Trow, 1957; Blau, 1956; Runciman, 1966; Hyman and Singer, 1968). John Urry (1973) provided a bibliography on reference group theory till the early 1970s, outlining a symbolic interactionist perspective toward the concept's past and future. Although the sociological interest in reference groups seems to have somewhat declined, recently the concept has been applied for analyzing social inequalities beyond national frames of reference (Whelan and Maitre, 2009). The influence of reference groups on an individual's attitude formation and behavior has mainly been examined in two theoretical traditions of research, on which we subsequently focus: On the one hand, symbolic interactionism and social psychology considered the normative importance of reference groups in the process of developing a self. On the other hand, structural and functionalist sociologists have analyzed the role of reference groups when material deprivation is estimated relative to other groups of social comparison. In the last section, the concept's contribution for developing the methodology of social research will be taken into account.

Normative Reference and the Development of the Self

Early anticipations of the reference group concept can be found in pragmatist theory and in symbolic interactionist's notions on the social self (James, 1890; Cooley, 1902; Mead, 1934), in Georg Simmel's studies on social groups (Simmel, 1908), and in William G. Sumner's distinction of in-group and out-group

(Sumner, 1940). As moralist reformer, William James characterized a 'potential' social self appraising itself with reference to others in "the pursuit of an ideal social self, of a self that is at least worthy of approving recognition by the highest possible judging companion, if such companion there be" (James, 1890: vol. 1, 315), highlighting the function of social distance when others influence our world views. Mead has encapsulated his central notion of the significance of a person's "generalized other" as "the generalized standpoint of the social group as a whole to which he belongs" (Mead, 1934: 138). He compared a person's role-taking, as that process generating a person's unity of the self, to the experience in a ball team (Mead, 1934: 154). According to George H. Mead, humans are able through symbols to communicate, to take on the role of the other, and become an object to oneself; this qualifies them to orient toward group norms and role performance when making judgments on their own (Mead, 1934: 138f.). While early in that process parents occupy an influential reference position, this then is shifted to peers and a generalized sense of society (Mead, 1934: 152ff.).

Examining students' development of political attitudes and behavior at Bennington College, Vermont, USA, Theodore M. Newcomb has differentiated positive and negative types of normative reference groups (Newcomb, 1943). The positive type involved the assimilation of group standards as a basis of self-appraisal; the negative one indicated that group norms may also be actively rejected and motivating the formation of counternorms, like in adolescent's rebellion against parents or hostile relations between groups. Newcomb systematically explored the ways in which college students related themselves to their community and with which consequences they did so. He observed that while freshmen tended to conservatism when measured against a number of public issues, this was less likely among junior and senior students; moreover, nonconservatism was more likely among those students strongly involved in college life and of higher status in college (Newcomb, 1943).

Hyman (1960) has emphasized the usefulness of the concept for developing public opinion research. Applying it to reference individuals as role models, he proposed that not only close friends and local neighbors, but also figures of public life as opinion leaders enact considerable influence. Moreover, he critically reflected opinion research's practical research routines that would benefit from a more extended concept of reference group theory. Already the study on voting behavior among citizens in the late 1940s in Elmira, New York, has shown that psychological identification with groups seen as important for oneself often predicts voting better than the mere measure of objective group membership (Berelson et al., 1954; Suchman and Menzel, 1955). This led Hyman to suggest that only the combination of judging one's location in class structure with expressing class awareness and subjective identification with a reference group can be treated as a powerful predictor of data on voting (Hyman, 1960: 394). Adumbrating that among nonmembers the ease of orienting oneself to a reference group norm is dependent on whether the social environment brings one closer to that group or not, and underscoring that in sampling large, heterogeneous groups we already deal with a differentiated structure, a set of norms, and also a group's perceived cohesiveness' (Hartley, 1960): The greater the perceived cohesiveness between norms of an actual membership group and those of an aspired reference group, the more likely an actor accepts the new group as reference group (Hartley, 1960).

From the standpoint of social psychology, Muzafer Sherif and Carolyn W. Sherif have introduced kindred terms such as points, scales, and particularly frames of reference as important in a person's attempt to gain acceptance by a specific reference group, and they applied the concept to issues of marginality and inconsistency in intergroup relations (Sherif and Sherif 1956: 143ff., 619ff.). Tamotsu Shibutani has characterized reference groups as perspectives available to the actor, defining a reference group as "a group whose outlook is used by the actor as the frame of reference in the organization of his perceptual field" (Shibutani, 1955: 565). While he considered the use of symbols, language, and communication in which this process is based, he did not take account of the structural arrangements that might condition these perspectives.

Social Comparisons and Material Deprivation

'The American Soldier' study (Stouffer et al., 1949a) has proved as particularly important for conceptually developing reference group theory. In a large empirical investigation of the life conditions and attitudes of US soldiers during World War II, Samuel A. Stouffer and his colleagues have been confronted with rather unexpected, counterintuitive findings: Soldiers in those branches characterized by less social mobility opportunities, like low-ranked officers, have reported greater satisfaction with their chances for promotion than their colleagues in the Air Corps where, objectively seen, career opportunities were much better. The authors explained this paradox with a 'theory of relative deprivation' proposing that the subjective feeling of deficiencies not only is a reflection of objective conditions but also depends on the respective standard of comparison. They assumed that low-ranked officers experienced greater satisfaction with their social situation because they compared themselves 'relative to others in the same boat with them' (Stouffer et al., 1949b: vol. 1, 251), among colleagues indicating those men of like-longevity, educational status, rank, and branch of Service, having not been promoted toward officership.

A theoretically oriented reexamination of these findings has been provided by Merton and Kitt Rossi (Merton and Kitt, 1950; Merton, 1957), examining the interplay between social theory and applied research from the sociological standpoint of structural functionalism. In systematically reflecting empirical cases from the 'American Soldier' study, the authors demonstrated that the theory of relative deprivation can be interpreted as specific case of a more general theory of reference groups of much broader sociological relevance. They emphasized the relative character of deprivation, where both feelings of dissatisfaction and of satisfaction result from standards of comparison with other groups situated in the social structure. "In general, then, reference group theory aims to systematize the determinants and consequences of those processes of evaluation and self-appraisal in which the individual takes the values or standards of other individuals and groups as a comparative frame of reference" (Merton and Kitt, 1950:

50f.). For Merton and Kitt Rossi, it has not been important that other groups are influential for a person's attitudes and behavior, but under which structural conditions membership and particularly nonmembership groups become influential. According to them, reference group selection is determined by institutional definitions of social structure, providing 'common comparative contexts for definition of the situation' among persons (Merton and Kitt, 1950: 62). At least a minimum of perceived commonalities, implying some knowledge of groups' norms and values, conditions that we take a particular reference group as a significant context for our judgments and evaluations (Merton and Kitt, 1950: 57). Dynamically seen, in case of multiple reference groups, persons have to make choices to resolve possible discrepancies and ambivalences arising out of contradictory norms and standards: In upward social mobility, the perception of, knowledge about, and adaption to norms and values of those groups are required in which one seeks acceptance and wishes to become a future member (Merton and Kitt, 1950: 57). The authors coined that phenomenon as 'anticipatory socialization' (Merton and Kitt, 1950: 87), a function of positive orientation to nonmembership groups, given a society's relatively open social structure. In the 'American Soldier' study, upward-mobility-oriented soldiers did not much conform to their immediate membership group's norms, but rather to the Army's 'official mores' and their more prestigious groups, in fact often having been at odds with in-group norms. Anticipatory socialization's consequences for a person result in finding readier acceptance by a group, making an easier adjustment to it, at the same time alienating from one's in-group. For the in-group to which a person belongs, that might be dysfunctional, thus putting members' positive orientation toward out-group norms under restraint (Merton and Kitt, 1950: 87). For the social system, reference group behavior's consequences are related to the legitimacy ascribed to institutional arrangements, also affecting the range of intergroup and interindividual comparisons (Merton and Kitt, 1950: 90). The authors intended to clarify the social processes sustaining or curbing orientations to nonmembership groups, and detach sociological concepts from a language of sentiment. In this way, Merton and Kitt Rossi have proved how reference group theory can be applied to a variety of areas of social life like class mobility, migration, social organization, and control.

Some years later, Merton (1957) examined empirical research that meanwhile had spread in the relevant field by specifying central concepts of groups and a provisional list of group properties. Drawing a distinction to reference group individuals as role models, he defined groups and group membership in terms of objective and subjective criteria: the former that social interaction among a number of people occurring in some patterned, frequent form, the latter that persons define themselves, and are similarly defined by others, as members of a group (Merton, 1957: 286). Structurally, Merton distinguished groups from collectivities, their members sharing a sense of solidarity while lacking social interaction with each other, and from social categories, persons with like social characteristics and statuses, but not necessarily a common body of norms (Merton, 1957: 299). Dynamically, he considered how boundaries of group membership and degrees of nonmembership can change in response to situational contexts. Concerning criteria for the latter, he drew on Simmel's notion of a group's 'completeness' (Simmel, 1908: 55), measured as a ratio of potential to its actual members, and indicated a direct relationship between a social group's completeness and power. Extensively he elaborated Simmel's notion of a group's 'capability to be surveyed' (Simmel, 1908: 50) as a group property relevant for regulation and control in social organization and the public, particularly when structurally hindered flows of information play an important role (Merton, 1957: 322, 336ff.). Merton's term of social visibility refers to the degree to which a person's status identity or a group's norms and role performance are readily visible or observable for others. Social visibility is also important to understand structural variability in knowledge about group norms, because that knowledge conditions to which extent a group can be taken as frame of normative reference at all (Merton, 1957: 322). Apart from visibility, Merton outlined objective eligibility and subjective attitudes toward becoming a member as criteria for nonmembership, resulting in structurally different kinds of nonmembers, for instance, 'candidates' or 'marginal men,' 'autonomous,' or 'antagonistic nonmembers' (Merton, 1957: 290). He reflected that vernacular language registers ex-members often with affectively toned terms that establish strong in-group versus out-group differentiations. Concerning determinants for the selection of reference groups, Merton has been carefully taking account of an array of empirical studies available on the topic, clarifying their conceptual implications for social structure, and pointing to the need of comparative studies of reference group behavior within disparate structural contexts (Merton, 1957: 306f.). However, he did not much address how his reference group theory is linked to social roles and to his general social theory. While his status- and role-set theory may be taken as part of his reference group theory, in reverse, Merton's reference group theory can also be regarded as "a consequent set of ideas about how status-and-role structures actually work" (Crothers, 1987: 93).

Reference Groups in the Methodology of Social Research

In order to provide an insight into how the concept helped to evolve the methodology of social research, from the abundance of studies on reference group behavior we consider only some, anticipated as combinatory cases along the axes of micro-macro- and structure-process analysis. First, the analysis of structurally induced conflicts and contradictions among multiple reference groups at microsocial level has proved to be important for conceptually developing role theory. In contrast to Merton's tendency to see conflicts as disturbing forces in need to be harmonized by mechanisms of social integration, his former student Ruth Laub Coser underlined the possibility of gaining individual autonomy, cognitive flexibility, and intellectual creativity in that process: Precisely because actors with 'complex' instead of 'simple' parochial role-sets frequently experience ambiguities among them, they develop competencies in dealing with these situations; this grants them higher individual autonomy in socially differentiated modern societies (Coser, 1975). Second, macrostructural conflicts between reference groups recently have found some attention in

analyzing social inequalities at national and supranational level. Still there are lively scholarly debates whether, by increasing globalization in times of crisis, people have begun to perceive themselves as part of larger stratification systems beyond a national framework, or whether their relative estimation of material deprivation rather depends on a national context (for instance, Whelan and Maitre, 2009). Third, taking microdynamics of shifting reference groups during one's lifetime into account, it has been examined how in adolescence, norms of peers as reference groups become more important than those of parents. Conflicting expectations and standards of parents and peers frequently create cross-pressure situations for adolescents; demanding standards of parental norms sometimes are reflected in those of a peer group as well (Rosen, 1955). Fourth, the dynamic macrocase of reference groups concerns the possibility that people dissatisfied with their social situation are motivated to engage in social movements with the potential to transform their social world. Urry (1973) applied reference group analysis to the empirical case of Indonesia in the first half of the twentieth century, in order to theoretically explain why actors experience dissent, organize themselves in social movements, and develop a mass revolutionary consciousness or not. He quoted Henry D. Thoreau who once has noted: "If a man does not keep pace with his companions, perhaps it is because he hears a different drummer" (Thoreau, quoted in Urry, 1973: 17). The need for understanding that drum as well has been convincingly outlined by Urry by emphasizing symbolic interactionism's fruitfulness in exploring the reference group concept. However, some of his suggestions for reformulating reference group theory seem to come closer to a structural functionalist tradition than he might have intended.

Methodologically seen, the reference group concept played an essential role in sociologically reflecting and bridging the two-way relationship of social theory and empirical research. Merton and Kitt Rossi (1950) outlined the concept's potential for structural and functionalist sociology, also distancing it from routines of small group research dominant in much social psychology of their time. The authors have frequently emphasized the concept's importance for comparative studies on social structure and patterns of reference group behavior of like-statused individuals. While they have explored the theoretical relevance of the concept for a broader scope of sociological research, conversely, reference groups also served as part of more abstract concepts' operational definitions. In order to get a clearer prospect of how to conduct research on Parsonian concepts of universalism and particularism in people's action orientation (Parsons and Shils, 1951: 76–88), Peter M. Blau (1962) interpreted them in the language of reference groups, hence necessarily referring to attributes of social structure, in contrast to cultural norms or personal motivational standards. The 'American Soldier' study's tremendous influence on an evolving discipline has also been reflected in the reader *Language of Social Research* (Lazarsfeld and Rosenberg, 1955); it also adumbrates how the broad use of the reference group concept apparently helped to develop procedures for social research. This alludes to generating social indices such as of mobility rates, group cohesion, social differentiation, and integration for studying the bearing of variations of social contexts upon the individuals' behavior situated in that social structure (Kendall, 1955; Merton and Kitt, 1950: 81ff.). The reference group concept also clarified the interplay of objective and subjective group properties in multivariate analyses on voting (Berelson et al., 1954; Suchman and Menzel, 1955) and the analysis of change through time in processes of public opinion and attitude formation (Lazarsfeld et al., 1955). More generally, Merton has taken account of the methodological perspective from which reference groups are examined: Since reference group behavior involves two-sided social relationships, similar to a theory of influence, it required a "simultaneous analysis both of the individuals adopting various reference groups and of the groups which provide these frames of reference" (Merton, 1957: 328). The reference group concept is useful for social research, because it provides an explanation both for the structural conditions under which social groups, particularly nonmembership groups, influence a person's values, attitudes, and behavior, and for the consequences of that process within the larger social structure.

This article is a revision of the previous edition article by N. Daniels, Volume 19, pp. 12872–12877, © 2001, Elsevier Ltd.

Abstract

The article deals with the notion of reflective equilibrium, understood as a state of coherence of our thoughts about one or more issues, resulting from a deliberative process of mutual adjustment of beliefs, principles, theories, and arguments. It focuses on its use as the central idea of a coherentist method of justification employed mainly in moral philosophy and elaborated in the writings of John Rawls. It discusses a variety of construals of the concept of reflective equilibrium, as involving a normative or descriptive approach, a wide or a narrow scope, a radical or conservative attitude, and a general or individual range of application. It summarizes the main general criticisms of the method, highlighting the problems of eventual circularity, lack of contact with reality and relativism, and more particular ones disputing the supposedly foundational character or questioning the reliability of the considered judgments appealed to in its pursuit, and pointing out the vagueness and the vacuity of the goal it aims at when it is presented in its wide version. A study of some of the main possible answers to these criticisms leads to the conclusion that the quest for a reflective equilibrium may not amount to much more than a regulative ideal, but it may still be regarded as the best methodological approach for ethics and for philosophy in general, when one takes into consideration the foundationalist and scientific alternatives. It seems to be especially useful for the adjudication of debates in applied ethics and especially in bioethics, where it allows us to avoid both deductions from abstract principles and an appeal to casuistic moves or extreme particularism.

The Concept of Reflective Equilibrium

A 'reflective equilibrium' is a state of coherence of our thoughts about one or more issues, resulting from a deliberative process of mutual adjustment of beliefs, principles, theories, and arguments. This deliberative process, involving the balancing and revising judgments at all levels of generality, until coherence is achieved, can be described as the 'method of reflective equilibrium.' It can be employed in any area of philosophical inquiry, but has become prominent in ethics, after its elaboration and application by John Rawls in the development of his moral and political theory. In fact, it can be interpreted as a particular form of a coherentist approach to the justification of beliefs and principles and contrasted to foundationalist accounts. In what follows, we shall try to present the main characteristics, advantages, and shortcomings of the method, focusing on the Rawlsian legacy. We will examine alternative construals of the idea of a reflective equilibrium, and we will take into consideration various positive and negative assessments of its usefulness with a view to providing a critical evaluation of its contribution to philosophical methodology.

The Method and Its Recent History

The term 'reflective equilibrium' was first introduced by John Rawls in *A Theory of Justice* (Rawls 1971, 1999a). However, the first clear description of the method of a mutual adjustment of beliefs and principles had been already provided by Nelson Goodman's in his *Fact, Fiction and Forecast*. Goodman argues that the principles of both deductive and inductive inference are justified through the process of bringing rules and particular inferences into agreement with each other. Thus, 'a rule is amended if it yields an inference we are unwilling to accept; an inference is rejected if it violates a rule we are unwilling to amend' (Goodman, 1979: p. 64). It would be pointless to try to provide a justification appealing to some form of foundation, self-evident starting points or a grounding basis.

Now, Rawls points out that the method of reflective equilibrium can be traced back to Aristotle's dialectical argumentation, which is described in his *Topics*, and according to many scholars is the main methodological approach adopted in the *Nicomachean Ethics*. He also compares it to Henry Sidgwick's argumentative strategy in *The Methods of Ethics* (Rawls, 1999a: p. 45n). Already in his *Outline of a Decision Procedure for Ethics*, published in 1951, he had discussed the problem of the justification of particular moral judgments by appealing to justifiable principles. He had observed that such principles "explicate the considered judgments of competent judges" and that the "reasonableness of a principle is tested by seeing whether it shows a capacity to become accepted by competent moral judges after they have freely weighed its merits by criticism and open discussion, and after each has thought it over and compared it with his considered judgments" (Rawls, 1999b: pp. 10–11). His conception of the method is specified in detail and plays a crucial role in the course of the construction of his theory of justice as fairness and of the justification of its essential components. The appeal to a hypothetical contract situation, which we are supposed to imagine through the thought experiment of an original position of rational contractors, leading to the formulation of basic principles of justice, as well as the use of the ideas of 'public reason' and of a 'well-ordered society,' at further stages of his reasoning, are tested within the broader methodological framework of the pursuit of a reflective equilibrium with our considered judgments about justice.

We are supposed to proceed as follows: We first try to identify a set of considered judgments about justice, that is, confident, stable judgments based on adequate information and arrived at through careful thinking protected from

distortions due to the interference of emotional factors, partiality or self-interest (Rawls, 1999a: p. 42; 1999b: p. 6). In fact, they are grasped and formulated at this stage, more or less immediately, without the appeal to any principles. We then seek principles which best 'account for' these judgments, and we soon find it necessary to engage in a process of mutual adjustment in order to remove divergences and overcome conflicts which we are likely to encounter. We realize that we have to move 'back and forth' between principles and judgments until we reach an optimal state where we no longer need to revise the principles we have come up with, or modify, 'prune,' or even give up some of the judgments the principles fail to account for (Rawls, 1999a: p. 18; Scanlon, 2003: p. 141).

However, the analysis just provided may give the impression that we are simply interested in looking for an equilibrium between a limited number of descriptions which 'more or less match one's existing judgments except for minor discrepancies' and we do not have to take into account 'all possible descriptions to which one might plausibly conform one's judgments together with all relevant philosophical arguments for them' (Rawls, 1999a: p. 43). It is the latter conception of the method which, according to Rawls, we are primarily interested in while engaging in the quest for a satisfactory moral theory, and its application could make possible a 'radical shift' of our judgments or principles. To be sure, it must be admitted that it is probably impossible to carry out fully the philosophical enterprise it seems to entail. The state of reflective equilibrium should be regarded as an unattainable ideal which we could only approximate in our indefinitely continuing work (Rawls, 1996: pp. 97, 385). The distinction between these two different accounts of the equilibrium one should aim at, already sketched in *A Theory of Justice*, is further elaborated in Rawls' later works. It is first presented as an opposition between 'narrow' and 'wide' reflective equilibrium in his *The Independence of Moral Theory*, published in 1974 (Rawls, 1999b), and its importance is emphasized again in *Justice As Fairness: A Reassessment* (Rawls, 2001: pp. 30–31). As we shall see, it is wide reflective equilibrium that becomes the central methodological notion adopted by contemporary philosophers.

Construals of Reflective Equilibrium

In fact, we have to distinguish among different construals of the concept of reflective equilibrium which have already been mentioned, or at least hinted at in our discussion so far. We are interested in highlighting interpretative options which must be taken into account when we try to deal with some of the main criticisms mounted against it.

Normative vs Descriptive

We have pointed out that the quest for a reflective equilibrium is invoked in a process of *justification* of beliefs and principles at all levels of generality and we have spoken of the deliberative process which we follow in our efforts to reach it. We are thus adopting a *normative* or *deliberative* conception, which goes beyond a mere description of our practices and aims at establishing the correctness of the judgments of principles in question (Scanlon, 2003: pp. 40–43). In fact, there are certain passages in *A Theory of Justice* where Rawls seems to be claiming that the principles arrived at in a state of reflective equilibrium help us *describe* our sense of justice in a way analogous to principles of grammar which reflect a sense of grammatical ability enabling a speaker of a language to recognize well-formed sentences (Rawls, 1999a: p. 41). However, the normative aims of moral and political philosophy such as those practiced by Rawls are different from the descriptive and explanatory goals of moral psychology or moral anthropology, even if philosophers should not ignore the results of the empirical investigations of the latter. In fact, this becomes clear when we realize that we have to broaden the scope of our procedure to include much more than the original set of considered judgments and the principles supposedly accounting for them. The descriptive construal seems to be based on a narrow understanding of the equilibrium to be achieved (Daniels, 1979: p. 258n).

Wide vs Narrow

We have seen that Rawls himself favored a *wide* rather than a *narrow* construal of his key idea. This construal has been further elaborated by Norman Daniels in his seminal paper *Wide Reflective Equilibrium and Theory Acceptance in Ethics* (Daniels, 1979, 1996a). Daniels speaks of an ordered triple of sets of beliefs, including sets of considered moral judgments, moral principles and relevant background theories, and describes four different levels of argumentative moves matching judgments, principles, and theories in ways which allow us to test alternatives and the feasibility of the principles selected. Daniels adds an important independence constraint, stipulating that "some nontrivial interesting portions of the set of considered moral judgments that constrains the background theories and of the set that constrains the moral principles should be disjoint" (Daniels, 1979: pp. 258–260).

An even more detailed survey of all the factors playing an important role in the procedure is provided by Michael DePaul in his critical analysis of the method of reflective equilibrium. Thus, we would have to take into account and seek a satisfactory match involving all of the following: (1) the inquirer's considered moral judgments, (2) background philosophical theories, such as theories regarding the nature of persons and personal identity, (3) background social scientific theories, such as theories regarding the role that a moral conception plays in a society, (4) the various alternative moral theories that have been developed, and defended, within the inquirer's cultural tradition, and possibly within alien traditions with which the inquirer's tradition has had to interact, and (5) the various philosophical arguments that have been constructed for and against all these moral conceptions (DePaul, 1993: p. 137).

Radical vs Conservative

As we shall see below, one of the criticisms addressed to defenders of the method of reflective equilibrium is related to a fear of conservatism. In fact, it may be thought that the pursuit of an equilibrium between moral convictions expressed

by considered judgments and moral principles entails an attempt to preserve the former by consciously or unconsciously selecting such principles that are *made* to account for them. Indeed, one may get this impression if one does not go beyond narrow reflective equilibrium. The 'partial,' limited fit, which could be achieved more or less easily at the first stage of matching of levels seems to involve minor adjustments. However, things are very different, if one is committed to the search for a wide equilibrium which, as we have already observed, often requires major revisions. In Rawls' words, "People have considered judgments at all levels of generality, from those about particular situations and institutions up through broad standards and first principles to formal and abstract conditions on moral conceptions… Although in order to get started various judgments are viewed as firm enough to be taken provisionally as fixed points, there are no judgments on any level of generality that are in principle immune to revision. Even the totality of particular judgments are not assigned a decisive role …" (Rawls, 1999b: p. 289). Moreover, philosophers who take seriously the far reaching implications of the commitment to the pursuit of an ideal, most probably unattainable state of wide reflective equilibrium realize its radical thrust which could bring about the reversal of well entrenched beliefs (Daniels, 1996a; Scanlon, 2003). Hence, it turns out that the method elaborated by Rawls and his disciples is quite different from its alleged predecessors, such as Aristotle's dialectic which does not allow for the possibility of a wholesale revision of reputed opinions (*endoxa*).

General vs Individual

As originally presented, the pursuit of reflective equilibrium concerns the individual subject of thought and action seeking to impose a coherent order on his or her beliefs at various levels of generality. Each person, and more specifically each citizen involved in reflection on political conceptions of justice, is invited to engage in a philosophical inquiry which proceeds by a continuous mutual adjustment of his or her considered judgments, principles, theories, and arguments. However, although Rawls defends a form of moral constructivism rather than realism, and despite the fact that, in his later work on political liberalism, he limits the universalist pretensions of his claims about a just society, he does think that we should try to "work up from the fundamental ideas implicit in the political culture, a public basis of justification that all citizens as reasonable and rational can endorse from within their own comprehensive doctrines. If this is achieved we have an overlapping consensus of reasonable doctrines and with it the political conception affirmed in reflective equilibrium" (Rawls, 2001: p. 29). In fact, if we assume that "each citizen in a well-ordered society has achieved wide reflective equilibrium" and since "citizens recognize that they affirm the same public conception of political justice," we will agree that "reflective equilibrium is also general: the same conception is affirmed in everyone's considered judgments. Thus, citizens have achieved general and wide, or what we may refer to as full, reflective equilibrium." In a well-ordered society, "the public point of view from which all citizens can adjudicate their claims is mutually recognized as affirmed by them all in full reflective equilibrium" (Rawls, 2001: p. 31, 1996: pp. 384–385n). As Rawls puts it, in a reply to Habermas, "this equilibrium is fully intersubjective: that is, each citizen has taken into account the reasoning and arguments of every other citizen" (Rawls, 1996: p. 385n).

We thus move to a construal of reflective equilibrium as involving the mutual adjustment of judgments, principles, theories, and arguments at an interpersonal, social level. This essential 'horizontal' expansion of the wide conception to include our fellow citizens, and more generally our fellow human beings, is crucial for overcoming any purely individualistic model of justification. It seems to conform fully to the requirement of reciprocity built in all contractualist normative theories. However, it should be noted that it renders the unattainable ideal of a perfectly satisfactory match or fit even more distant, broadening the 'indefinitely continuing process' (Rawls, 1996: p. 97) in the pursuit of expressions of an overlapping consensus, extending to well-ordered societies on a global scale.

Criticisms of Reflective Equilibrium

General Worries about Coherentism

Some of the general objections to reflective equilibrium are instances of familiar strictures directed against all coherentist conceptions of justification. At this point, we shall present them briefly, summarizing some of the main responses which have been provided by supporters of such conceptions and can also be invoked in the case of reflective equilibrium.

One is often reminded of the *circularity* besetting the reasoning procedure which is employed in the pursuit of reflective equilibrium. It is a well-known problem recognized by defenders of coherentism and by Goodman himself in his original description of the method (Goodman, 1979). However, it can be pointed out that the entire set of interconnected argumentative moves, deployed in all directions, which aim at balancing and matching elements in a nonlinear manner do not form a vicious circle. The justification we are seeking is achieved precisely when we manage to construct a web, the nodes of which hold together in a way that does not require further adjustment.

Another reason for wanting to reject the method is the impression that the entire set of judgments, principles, theories, and arguments, in wide reflective equilibrium does not bear the appropriate relation to the moral reality it is supposed to reveal. Indeed, as is the case with coherent sets of beliefs, a typical complaint is that *no contact with reality* is established through the strengthening of internal relations leading to equilibrium. On the contrary, it seems that the reality itself we are interested in is *constituted* by the entire set of the very elements we try to fit in the best possible way. Such an interpretation of the proposed approach to the various dimensions of moral thinking and acting at all levels seems to be supported by Rawls' defense of a constructivist account of morality and by his reluctance to speak of moral truth. Actually, there is no serious objection to the method, insofar as one may be happy to embrace such a version of antirealist constructivism.

However, it should be pointed out that the conception of reflective equilibrium as such does not necessarily imply antirealism. The state of coherence attained may be regarded as

evidence of truth. In fact, some of the philosophers who have recently endorsed a rather strong, naturalistic version of moral realism do not hesitate to appropriate the method of reflective equilibrium (Boyd, 1988; Brink, 1989). Their work shows clearly that a coherence theory of justification is not always accompanied by a commitment to a coherence theory of truth. Moreover, some philosophers have argued that even the latter is compatible with some form of realism (Dancy, 1985).

A parallel and complementary worry that is usually expressed is based on the fear of the *relativism* that may have to be accepted if we recognize the possibility of the existence of many sets of judgments, principles, theories, and arguments in states of equilibrium, which may all be equally acceptable. In other words, we are confronted by the objection of the possibility of many equally coherent sets of beliefs, quite familiar from debates in the theory of justification. Now, the idea of a point of maximal coherence, or of a perfect mutual adjustment which we may never be able to reach, apparently endorsed by Rawls in his mature work, seems to imply the transcendance of all actual equilibria reflecting the development of subjective or communal viewpoints which most probably require further elaboration. Even if we can never reach it, as Rawls puts it, 'we may get closer to it in the sense that through discussion, our ideals, principles and judgments seem more reasonable to us and we regard them as better founded than they were before'(Rawls, 1996: p. 385). Of course, we strive for consensus, we hope for a convergence of views toward the full and general, wide equilibrium we seek, and we cannot be certain that this can be realized, even if we pursue our investigations indefinitely. Here, all we can say to skeptics who do not seem to acknowledge any signs of such a convergence concerning moral and political matters, is that the pursuit of reflective equilibrium, which we propose to adopt as the most reliable nondogmatic procedure, does not guarantee that our expectations would not be frustrated.

Particular Objections to Reflective Equilibrium

Apart from the above general challenges to the method of reflective equilibrium as a coherentist approach, there are complaints about the particular concepts appealed to in the procedure advocated and followed by Rawls. There are two basic lines of criticism focusing on the notion of considered moral judgments, which seem to point in opposite directions:

On the one hand, it has been claimed that the use of considered judgments hides an implicit dogmatic commitment to intuitive starting points that we wish to preserve and eventually justify by the proper selection of principles. Thus, it is thought that there is a *disguised intuitionism* of subjective character covered behind the requirement to draw on beliefs that we claim to be testing. This accusation has been put forth by philosophers, such as utilitarians, who prefer different, straightforward ways to isolate and defend their basic principles, from which they shall claim to derive rational conclusions, however counterintuitive they may be (Hare, 1973; Singer, 1974, 2005). In fact, we have already referred to the suspicion of conservatism which Rawls was trying to dispel, explaining that the considered judgments in question are not supposed to be treated as secure and are not immune to revision any more than the principles they test and are tested against. Critics here fail to understand the importance of the perspective of wide reflective equilibrium and of its radical character.

On the other hand, we also encounter the complaint that the considered judgments are not secure enough to be trusted in the pursuit of our investigations. Their *degree of credibility* is not sufficient to provide us with a solid basis that will help us to proceed to the search of principles which will account for them and will presumably be accepted after the necessary work of mutual adjustment (Brandt, 1998). Here, we may once more detect foundationalist aspirations involving the requirement of an appeal to 'facts' and 'data.' However, as Daniels correctly points out, considered moral judgments are unfavorably contrasted to 'observation reports' which possess higher initial credibility, and it is not realized that they are more like 'theoretical statements' than observation reports. The parallel between ethics and science is pushed too far and we miss the crucial difference in the degree of theory dependence of the judgments and beliefs we begin with respectively in the two cases (Daniels, 1979: pp. 269–272).

One of the most interesting criticisms of the method is arguably what can be considered to be one of its advantages, namely its flexibility and its extension making it possible, at the end of the day, to accommodate, to integrate and harmonize all kinds of judgments, principles, theories, and arguments in a vast holistic perspective. Even certain self-evident principles inherited from the intuitionist tradition could find a place in the broad set of disparate elements at equilibrium, provided they are introduced without the support of any claim of independent warrant, presumably established before engaging in the balancing and matching procedures that are imposed by the directives of the proposed method. Moreover, although they must be denied the infallibility of necessary truths, we may even be willing to attribute to them some form of relativized necessity, if they have 'earned' it at the state of equilibrium, after having been subjected to testing against considered judgments and other moral and relevant nonmoral principles. In other words, the generality and the vagueness of the concept of equilibrium, the excessive openness, the breadth and the lack of determinacy of directives for the deliberative procedure of reflective 'adjusting,' 'matching,' or 'fitting' – problematic features, analogous to those of the idea of coherence – give rise to worries concerning its correct application. If anything could eventually be adjusted – after appropriate radical revisions – to anything else, within a vast framework of considerations at various theoretical and practical levels, one fears that the very ideal of reflective equilibrium might turn out to be *vacuous* and its usefulness might prove mostly *negative* in blocking the employment of unjustified foundationalist methodological options.

A final criticism which goes along with a recognition of the substantial virtues of a method of radical and wide reflective equilibrium and its advantages over available, traditional alternatives is elaborated by Michael DePaul in his *Balance and Refinement: Beyond Coherence Methods in Ethics* (DePaul, 1993). In fact, although DePaul's approach is not a simple correction or extension of the amended Rawlsian model in its wide conception, it can in a sense be regarded as a descendant. DePaul argues that the method is very *intellectualistic* and

mechanical. It cannot account for an experiential dimension of crucial moral significance that is not captured by the adjustment of judgments, principles, theories and their inferential or evidential links. Their equilibrium does not secure they are always warranted. He proposes to replace it by an analogous conception of justification of beliefs and further guidance of our thought, which partly replaces, rather than supplements, the reasoning procedures of the method of reflective equilibrium by a more general balancing of intellectual and affective factors. He thus stresses the need, not only for a careful rational balancing of elements, but also for the continuous refinement of our sensibility through the enrichment of moral experience afforded by various sources which include fiction and works of art (DePaul, 1993).

Further Applications and Prospects

As we saw, it might be argued that given the generality and the vagueness of the concept of a reflective equilibrium, as well as its unattainable character, it is preferable to speak of a regulative ideal of a method, rather than of a properly specified method with clear directives. To be sure, as we have known since the time of Aristotle, it would be foolish to seek scientific or mathematical determinacy and precision in the ethical domain.

In any case, despite the fact that the worries we have sketched in our survey of objections and criticisms do persist and the responses provided may not be fully satisfactory, the method or methodological ideal is well entrenched, if not dominant, in contemporary moral and political philosophy. It is naturally employed in domains of ethical inquiry which require the combination of different levels and fields, but also call for some form of direct application in practice. We have already noted its popularity in metaethics, more particularly among naturalist defenders of moral realism. We may also acknowledge its importance for the adjudication of methodological debates in applied ethics and especially in bioethics, where it allows us to avoid both deductions from abstract principles and appeal to casuistic moves or extreme particularism. We can thus seek a complex synthesis of 'top-down' and 'bottom-up' approaches, following a wide conception of reflective equilibrium of a variety of considerations at all levels (Daniels, 1996b; Van de Burg and Van Willigenburg, 1998). The lesson we shall draw from recent applications of the method is that answers and solutions at all levels of generality, from the most general metaethical theory to the concrete and immediate judgments supporting practical decisions, are best justified if we take into consideration, directly or indirectly, holistic 'packages.'

Moreover, reflective equilibrium could be regarded the most plausible general coherentist approach to all areas of philosophical thinking, perhaps by default; provided, of course, one is not a skeptic and is also willing to jettison rationalist accounts or scientistic and reductionistic conceptions, invoking either a priori or empirical secure foundations (Cummins, 1998; DePaul, 1998). In any case, those who are eager to challenge it must do better than simply reaffirm a dogmatic commitment to foundationalism of one or another variety.

Abstract

Reflexivity and reflexive practice are terms that have become pervasive in social work literature in recent years, but that remain contested and ill-defined, often being conflated with reflection and reflective practice. It is argued here that while the reflexivity literature demonstrates a generic concern with the critical analysis of practice in its social context, a finer grained distinction can be made between sociologically informed writing about 'practicing reflexivity,' and a more cognitive and process-oriented literature about 'reflexive practice.' Together, these approaches to practice offer insights that subvert the conventional understandings of expert practice and illuminate the situated nature of social work, but as yet they fall short of a unified or empirically tested theory of practice.

Introduction

> There's a lot of people talking, there's mighty few that know…

These words were sung by the blues artist Sonny Boy Williamson and the same might be said about writers about the concept of reflexivity and its relation to social work. Arguably, social work has a tradition of borrowing concepts from sociology and social theory and applying them to theories of practice, usually somewhat later than they were current in social theory and with some imprecision in their usage (Stenson and Gould, 1986). A review of the use of the concept of reflexivity in social work writing (D'Cruz et al., 2007) found a general lack of clarity in the use of the concept and, in particular, a lack of differentiation from the concepts of 'reflection' and 'critical reflection.' Other social work writers seem either to evade the issue of definition of reflexivity or perhaps assume that readers have an implicit understanding of what is meant; a recent chapter titled reflexive practice does not only omit a definition of reflexivity, but the term also does not occur in the text of the chapter (Doherty and White, 2012). Another definitional maneuver is to argue that in social work reflective practice is associated with professional practice, whereas reflexivity is associated with research methods (Wilson et al., 2008: p. 12). This is tidy but seems difficult to sustain, not least because some writers about reflexivity emphasize the overlap between practice and research methods, particularly those derived from feminist and critical qualitative research (Shaw and Gould, 2001).

An expectation that everyone knows what is meant by reflexivity is particularly problematic as an examination of the social sciences reveals a more diverse and contested usage of the term than the social work literature seems to assume. A few examples illustrate the point. Reflexivity is a widely used concept in economics and is associated with the ideas of economist George Soros (1987), who challenges orthodox theories of market equilibrium, arguing that markets follow self-reinforcing cycles between prices and expectations leading to boom and bust, i.e., disequilibrium. From this reading, reflexivity is not necessarily a benign or progressive force. However, the implication that outcomes cannot be predicted from aggregated macroeconomic data because of the unpredictability of human reactions to events does echo some of the social work critiques of positivism and evidence-based practice (Gray et al., 2009). In anthropology, reflexivity has come to have two distinct meanings, one that refers to the researcher's awareness of and analytic focus on their relationship to the field of study, and the other that attends to the ways that cultural practices involve consciousness and commentary on themselves (Clifford, 1997; Geertz, 1987). These anthropological interpretations of reflexivity may have more apparent relevance to social work, although they do not imply a unified field of discourse.

This article will review the ways reflexivity has been used in the social work literature and attempt a provisional consideration of whether any general synthetic lessons can be drawn. In their review of the literature, D'Cruz et al. (2007) argue that they can identify three 'variations' (their term) in the usage of reflexivity in the social work literature: the first focuses on ideas of self-actualization, the second emphasizes critical awareness of the self in action, and the third majors on the role of the self in the creation of knowledge. This summary does not do justice to the depth of their argument but, it is not clear that their typology is analytically sustainable. There seems to be considerable overlap in these categories around the repeated emphasis on the centrality of self. This seems somewhat ironic given that a central argument of at least some protagonists of reflexive practice is the 'decentering' of self (e.g., Taylor and White, 2000: pp. 43–44). A German social work scholar, Kessl (2009), constructs an alternative typology. He argues that debates within social work about reflexivity are located within analyses that have been emerging since the 1970s around the transformation of the welfare state, and that these contributions reflect contrasting methodological (and inherently epistemological) standpoints. He identifies these standpoints as deriving from critical theory, radical constructivism, and ethnomethodology, although he concedes that the terrain of the debate is complex and not easily amenable to simple categorization. This article will take a different approach, accepting the conclusion of these reviewers that reflexivity remains a contested and vaguely defined term, but that a basic and pragmatic distinction can

 http://dx.doi.org/10.1016/B978-0-08-097086-8.28075-6

be made between those who can be described as 'practicing reflexivity,' which primarily operationalizes the implications of practicing within a sociologically informed understanding of modern reflexivity, and 'reflexive practice,' which situates social work practice within a more psychological, cognitive, and process-oriented approach to expert practice. Again, the boundaries of this distinction may be permeable, but it offers a broadly robust method for categorizing the literature. But first, before one considers what 'practicing reflexivity' and 'reflexive practice' are, what are they not?

Reflexivity and Reflexive Practice: What Are They Not?

The argument that social work requires the use of self within a reflexive awareness of the sociological and structural context of practice has an important provenance, and it would be an error to see it solely as a postmodern phenomenon. Even within the classic 'social casework' tradition, although the specific terminology of reflexivity had not arrived, it is clear that the psychosocial approach dealt with the 'person-in-situation,' a gestalt that indicated individuals' (including the social worker's) transactions with the social systems of which they were a part (Hollis, 1970). Radical social work of various hues, in part a reaction to the psychological individualism of traditional casework, took on and developed the Marxist concept of 'praxis,' the idea of practice being constituted both by action and reflection (Leonard, 1984). Although strongly indebted to the class analysis of Marxism, radical social work also drew on critical theory and aspects of psychoanalysis to theorize social work as engaged in raising, "critical consciousness of the nature of the services and how they define both the recipient of the service and the state worker within it" (Leonard, 1984: p. 215). Praxis was also a defining element of approaches to social work influenced by Paolo Freire (1970), which theorized 'conscientization' as a collective process of consciousness raising. Similarly, the Women's Movement and those who developed feminist standpoints in social work stressed the primacy of connecting the personal with the political to raise consciousness, "the process of transforming the hidden, individual fears of people into a shared awareness of the meaning of them as social problems" (Mitchell, 1975: p. 61). Feminist social work also connected with the emergence of antiracist and antidiscriminatory perspectives that acknowledged the multidimensional nature of oppression and the need for practitioners to acknowledge their own position within relationships of power (Dominelli, 1988, 2002).

More recently, the promotion of reflexivity as a standpoint in social work has been a way of steering a route between the Scylla of reflective practice and the Charybdis of evidence-based practice (Sheppard et al., 2000; Evans and Hardy, 2010). Although there is also a tradition using the terminology of reflection associated with psychodynamic perspectives (Mattinson, 1975; Yelloly and Henkel, 1995), reflective practice as a concept is generally taken to have been imported into social work from the research and writing of Donald Schon (Gould, 1989; Papell and Skolnik, 1992). Schon (1983) offered a bottom-up critique of the technical rational model of professional activity that characterizes practice as deductively drawn from formal, scientific knowledge. Instead, practice is represented as a form of artistry where practitioners iterate their own theory of practice through direct engagement with problems and the conscious deployment of reflection-in-action. The formal canon of knowledge may inform and contextualize practice but theory is understood as inductive and idiographic. In social work, the emergence of reflective practice seemed to gain traction in the 1990s not least from what has been described as the crisis of the professions: growing public skepticism about the infallibility of professionals, a reduction in automatic deference to experts, and sustained criticism of the adequacy of qualifying educational programs to prepare professionals for practice (Gould, 1996).

Aspects of this critique share some common ground with the theories of the risk society and late modernity (e.g., Webb, 2006), which the author will consider in relation to reflexivity, although the intellectual provenance is distinct. Some social work writers have subsequently taken reflective and reflexive practice to be interchangeable terms, and particularly so in regard to 'critical reflection,' a variant that draws heavily from critical theory and is particularly associated with the writing of Fook (e.g., Fook and Askeland, 2006). However, protagonists of reflexive practice have identified shortcomings and problems with reflective practice for which they offer reflexivity as a corrective. Evans and Hardy (2010) describe the reflexive critique of reflection as being the view that the latter is essentially concerned with individualistic psychological processes and overlooks the social, political, and ethical dimensions of social work:

> Thus, the notion of reflection has expanded into the wider notion of reflexivity, the key distinction being between the former's focus on internal self-awareness and the latter's emphasis on ensuring that the role that external, contextual factors play in informing individual subjectivity is specified. (Evans and Hardy, 2010: p. 124)

Thus, reflexivity expands the parameters of reflection. However, reflexive practice positions itself not only in relation to its refutation of aspects of reflection, but also in relation to its counterfactual, evidence-based, or empirical practice (Taylor and White, 2000). Again, there is a rejection of linear procedural and technological solutions to describing what constitutes 'best practice' and, as with the reflective critique of technical rationality there is a concern to identify the qualitative aspects of practice. The character of typical presenting problems confronted by social workers is that they are ambiguous and uncertain (Gould, 1996; Webb, 2006). Consequently, given the socially constructed nature of the 'problem,' formal algorithms derived from experimental research cannot be applied in the prescriptive fashion that is espoused in evidence-based medicine. Protagonists of reflexivity are vocal in their espoused rejection of what is usually described by them as positivism, and they are also usually careful to qualify this rejection

with a confirmation that formal knowledge remains relevant to practice:

> If we are arguing that the knowledge produced by the technical/rational approach and advocated by the EBP movement does not consist of neutral and detached observations of the real world, does this mean that it is worthless and should be disregarded? Most certainly not. (Taylor and White, 2000: p. 189)

The reflexive practice literature refers heavily to the sociology of scientific literature (e.g., Collins, 1985; Gilbert and Mulkay, 1984; Latour, 1999), which shows that the practice of science, including laboratory-based science, involves more than following stepwise scientific procedures, and is characterized by the insertion of judgment, improvisation, and communication through social networks. Reflexive approaches, whatever their differences, share a concern that empirical practice again underestimates the variability and uncertainty of the social environment of social work practice.

Reflexivity and Research

There is a long-standing, and at times fierce, debate in the social work literature as to whether doing direct practice is analogous to the process of doing research (Gilgun, 1994; Padgett, 1998), with specific reference to some of the similarities with qualitative research methods (Sheppard et al., 2000). For example, some writers on social work research position debates about reflexivity within wider postmodernist debates about fragmentation of social structures and the emergence of the 'risk society.' Reflexive modernity involves the management of risky situations under conditions of such complexity that outcomes cannot be predicted. The literature on reflexive practice, although not conflating research and social work intervention as forms of practice, does make explicit reference to the legacy of certain research traditions, particularly feminist and qualitative research. The latter makes little use of standardized instrumentation, the researcher is the main instrument of doing the research, and thus, the subjectivities of the researcher, those being researched, and their interaction are strongly foregrounded. Some sociologists have expressed their concern at the self-indulgence this can generate, as Becker (1993: p. 226) famously commented, "some researchers specialize in philosophical and methodological worry as a profession," and one shall see that some critics of the reflexive turn in social work echo this cautionary note.

Practicing Reflexivity

At the heart of much of the writing about reflexivity in social work is a project to build on the writings about 'reflexive modernity' developed by Beck (1992) with subsequent contributions of other sociologists such as Giddens (1990) and Lash (1994). A key contributor to social work writing about reflexive modernity has been Ferguson (2004) who, drawing specifically on the theoretical contributions of Beck and Giddens, argues that individuals now have unprecedented opportunities to shape their own lives. Reflexivity is characterized as a project of the 'self,' made possible by the fragmentation of the grand narratives that derived from modernity, which enables people under appropriate conditions to reflect on their actions and shape their identities. Ferguson suggests that these opportunities are potentially available to the clients of social workers to define their own needs rather than be subjugated by definitions imposed by experts, and thus are able to influence services to make them more appropriate and responsive to their expressed needs. This analysis is most extensively developed in relation to child protection services (as is most of the reflexive practice literature), in relation to which Ferguson suggests that women and children might be able to use services proactively and creatively to find protection from abusive relationships and avoid the damage and trauma generated by abuse. Ferguson redefines clients as "creative reflexive citizens" and he recasts the responsibilities of social workers and others who are part of child protection services to resist received constructions of the client that emphasize pathologies and deficits, in favor of engagement with strengths.

Some critics (e.g., Scourfield and Welsh, 2003; D'Cruz et al., 2007) criticize Ferguson for holding an almost unsociological view of the individual, presenting a view of social work clients as autonomous agents and downplaying their position vis-à-vis structural relations of power and class inequalities. Critics of Ferguson sometimes cite Kondrat (1999) who had already critiqued reflexive self-awareness as an orientation to practice as it emphasizes individual psychological processes at the expense of wider social relationships. Kondrat drew attention to another aspect of Gidden's (1990) writing, structuration theory, sometimes referred to as the 'double hermeneutic,' in which the goal of critical reflexivity as a form of practice aims for social workers to operate with greater awareness of structural relations and their opportunities to influence them. Ferguson might reasonably feel these criticisms to be overstated or even unfair; his most extended discussion of reflexivity and reflexive modernity and child protection (2004) comments extensively and repeatedly on the influence of class and gender on the nature of child protection practice. His analysis suggests that the challenge for social work is to go beyond compliance with forms of social control that are conventionally scripted by child protection systems, to work alongside clients in what he refers to as 'life planning,' supporting people to overcome the roles and destinies conventionally assigned to them. Reflexivity is thus a strategy that can be imparted to people who receive services to help them achieve emancipation and self-actualization, an ambition that has echoes with the work of radical adult educators such as Friere (1970) on conscientization (see above) and Mezirow (2009) on transformative learning.

Ferguson's writing on reflexive modernity, as already indicated, is primarily located in theoretical contributions to the understanding of the risk society drawn from Beck, Giddens, Lash, and others. This contrasts but overlaps with developments in the theorization of health and social care practice that more particularly focuses on the contributions of Foucault,

poststructuralism, and discourse theory (e.g., White, 1997; Taylor and White, 2000). As would be anticipated from Foucault's preoccupations with knowledge and power, processes of knowledge creation, and disciplinary practices, the work of White and others emphasizes the importance for social work of processes of critical analysis and deconstruction of the scenarios and interactions in which practitioners participate, to reveal terrains of power and influence. This contrasts with Schon (1983) and reflective practice where it is suggested that reflection takes place when unanticipated and nonroutine problems are encountered, so the objective of reflexive practice is to destabilize taken for granted assumptions that accompany and are embedded in routine practice and language. Methodologically, this standpoint draws extensively from ethnography and autoethnography as processes of social analysis. Indebtedness is also demonstrated to feminist perspectives and conversation analysis. The lessons of earlier ethnographies of social work practice are also discernible, for example, Dingwall et al.'s (1983) study of child protection practice, which drew attention to the inherently ambiguous and contested nature of 'evidence' in relation to the detection of child abuse.

Reflexive practice from within this perspective of the examination of making meaning, goes beyond the sense of reflection as disparagingly described by Woolgar (1988) as 'benign introspection.' A point of departure in the approach is that in many of the situations encountered by social workers and those in allied professions, there will be conflicting and disputed accounts of events: a baby is admitted to Accident and Emergency with extensive scalds, is this because the thermostat on the domestic water failed and the parent had not realized that the bath water was scalding, or had the parent deliberately punished the baby by immersing the baby in hot water, as suspected by the health visitor? As Dingwall et al. (1983) had found, physical injuries unless directly witnessed invariably require interpretation and judgment, and do not speak for themselves. In asserting their own versions and claims to truth in relation to these events, actors will draw on a repertoire of rhetorical devices to press their own view. For Taylor and White (2000), this is inherent in the nature of practice, and rather than proceed on the basis of the illusory certainties of evidence-based practice, they enjoin practitioners to cultivate a critical analysis of the forms of making sense they encounter. Reflexive practice as elaborated from this standpoint does not lead to the formulation of particular or distinctive methods of intervention but encourages practitioners to cultivate a skeptical interrogation of the ends that are implied by an intervention and the forms of power that are reproduced. For example, does a particular variant of a parent-training program mobilize a normative and gendered view of the role of a parent, and does it undermine the self-efficacy of a parent who undergoes it? And why?

Reflexive Practice–Heuristic and Process

In contrast to these sociologically oriented versions of reflexivity, some writers have treated reflexivity as a skill or capability, which, to a degree, is a disposition possessed by everyone, but which can also be transmitted and refined into higher levels of competence. Collins and Evans (2007), for example, identify reflexive ability as a skill that is part of a generic skill set that is not dependent on an individual's specialist subject knowledge, but is a precondition to developing expertise. Collins and Evans' field is the sociology of scientific knowledge, but the view of reflexivity as a heuristic (an experientially based strategy for problem solving) emerges in some areas of social work writing about epistemology or processes of knowledge creation. For example, Sheppard has argued in a series of theoretical and empirical contributions that reflexivity includes a set of cognitive skills that can be developed. Again, he draws analogies with the teaching of methodology to research students to equip them to conduct rigorous research so the development of concepts and classifications of reflexivity could enable this to be taught as a discrete knowledge area for social work practice. This process knowledge would inform the conduct and recognition of good practice (Sheppard et al., 2000: p. 469).

For Sheppard, the concept of reflexivity in social work emphasizes two essential conditions, that the social worker is an autonomous thinker who is able to assess, respond, and initiate action, and is aware of the socially situated nature of their relationship to the service user (Sheppard, 1998). His research suggested that practitioners demonstrate differential or variable levels of capability in relation to reflexivity but that an 'ideal type' of reflexive practice would contain a series of cognitive processes, starting from scrutiny of information at an initial referral stage, through critical appraisal of that information to generate hypotheses or questions relating to alternative formulations and ultimately strategies for intervention. Like Ferguson (2004) or White (1997), he stresses the ambiguity of much preliminary information and the need for a process of iterative critical appraisal as a situation evolves and new information is revealed.

Models of reflexive practice that build on theoretical insights to provide guidelines for practice intervention are relatively scarce and undeveloped. One model of reflexive practice has been developed by New Zealand and Australian academics and practitioners specifically geared again to the context of child protection practice (Connolly et al., 2006). They argue that child protection takes place at the intersection of several cultures: cultures of professional identity, family, ethnicity, and so on. Thinking about cultures, they argue, is particularly susceptible to the effects of stereotyping, with negative consequences for children and families. They propose a culturally reflexive model (CRM) to challenge reductionist thinking and to make practice more culturally responsive. Unpacking CRM, it is evident that reflexivity in this context is directly theorized from the approach of Fook and others toward 'critical reflection,' which, as was seen is sometimes taken to be synonymous with reflexive practice. Connolly et al. (2006) describe a three-phase model of practice, which begins with identifying personal, family, and societal cultural attitudes; proceeds through critical reflection of those attitudes to uncover and challenge the assumptions and aspects of power they

embody; and, third, putting into practice new approaches ('reflective outcomes') that are more productive and effective in protecting children. Connolly and her colleagues assert the importance of developing theories such as theirs as resources that social workers can draw on to improve practice.

Payne (2009) suggests that practice can be conceptualized as a 'reflexive cycle' that connects a series of reflexive activities each of which involves a level of engagement with the self: self-reference, self-analysis, self-interpretation, and self-criticism. The cycle begins with observation and appreciation of the context within which the practice takes place, analysis takes place of the interaction and communication between those involved in the situation, the worker supports others to understand how they communicate, and the impact of their interaction and changes take place in communication as a result of the understandings that have emerged. Payne illustrates these generic processes with an example of his own practice with a married couple coming to terms with the husband's serious illness. As Payne himself indicates, an inherent problem with suggesting a model of intervention that claims to be reflexive is that paradoxically it imposes a linear, reified process on activities, which, by definition, are supposed to be flexible and improvisatory (Payne, 2009: p. 169). Payne's example of the reflexive cycle also seems to be predominantly psychological, not dissimilar to models of reflective practice, and lacks the sociologically situated dimension that is so prominent in more theorized accounts of reflexive practice that engage explicitly with social structures and power relationships.

Discussion

It was seen that there is no clear consensus around the meaning of reflexive practice, beyond a claim that practice should be consciously located within an awareness of the impact of the self and/or the broader sociological context of practice. Can this be said to constitute a new paradigm of practice, a distinct break with the traditional concerns of social work with locating the person within their social environment, and cultivation of the use of self within practice? Is the idea of social work promoting in clients the status of 'reflexive active citizens' really very different from the approach to challenging deficit models of practice found in the radical social work literature discussed above and in 'strengths' models of practice (Saleebey, 2009)? Scourfield and Welsh (2003) have argued that the reflexivity thesis (particularly within the 'practicing reflexivity' variant) is simply the 'same old story' presenting well-established truisms about the nature of social work as a form of social control, but presented within new theoretical frameworks. Using the example of child protection practice, and drawing heavily on Scourfield's ethnographical research, they show that the class-based and gendered nature of social work practice is only too manifest and overt, without needing deconstruction through the theoretical prism of reflexivity. Inequalities of power and governance of the family by professional experts, and the sanctions experts can invoke, are well understood by the subjects of social work assessment and intervention; they do not need to have them revealed through processes of 'life-planning,' as advocated by Ferguson. Indeed, Scourfield and Welsh claim that Ferguson misconceives aspects of Beck's theory of the 'risk society,' namely, that Beck implies reflexivity produces 'more of the same,' whereas the term 'reflection' denotes critical appraisal and change, which is an inversion of the critiques of reflective practice proposed by proponents of reflexivity (Scourfield and Welsh, 2003: p. 403).

Conclusions

In this article, 'practicing reflexivity' has been contrasted with 'reflexive practice,' the latter encompassing the social work theorists who emphasize the various cognitive and affective components of micropractice. Here, the critics have contended that such approaches engender a sense of self-importance of the practitioner, and self-justification rather than self-critique. This is associated with a concern that an approach that emphasizes uncertainty and ambiguity in the analysis of social relations can lead to a situation of endless relativism, where nothing can be established or agreed with sufficient certainty to provide a basis for action. Not least, the protagonists for reflexive practice are challenged to develop a research agenda that validates, or otherwise, the effectiveness of its contribution, and can demonstrate that it makes a difference to outcomes for service users. A central plank of the reflexive thesis has been sustained skepticism of evaluation research and the 'what works?' agenda. This has resulted, in so far as reflexive practice has promoted an evidence base, in a preponderance of qualitative, process-oriented studies. The challenge for reflexive social work becomes one of reinterpreting the nature of outcome-based research to support more pluralistic and participatory definitions of what constitutes an outcome, and how and by whom it can be measured (Kessl, 2009).

'Reflexive practice' and 'practicing reflexivity' are works in progress, having entered the lexicon of social work relatively recently. These fields of scholarship are making various contributions to the development of social work that are becoming part of a broader consensus: not least they draw attention to the dangers of taking experts to be infallible and warn against an overemphasis on the attention to psychological aspects of practice without attention to social context. Also, reflexivity attempts to steer a course between the over-subjectivity of reflective practice and the depersonalized reductionism of evidence-based practice (Healy, 2005). Where should reflexive practice look in terms of its further development? Kessl (2009) suggests that the imperative is to develop an understanding of social work that reflects the realities of the postwelfare state that has been emerging since the 1970s. Social work emerged as a component of the welfare state in response to the relationships between the state, civil society, and the private citizen that was characteristic of capitalist societies in the late nineteenth century and twentieth century. Internationally, social work is having to redefine itself in relation to global economic forces that fragment traditional solidarities and introduce

the logic of the market to every aspect of social protection (Dominelli, 1999; Pugh and Gould, 2000). Within this political context, reflexive social work is at least a resource sensitizing social workers against taken-for-granted thinking and being co-opted into implementing social policies that commodify welfare and reinforce social exclusion and inequality.

Reflexivity in Anthropology

Abstract

Reflexivity has been an essential dimension of cultural and social anthropology's emblematic method of inquiry: ethnographic fieldwork and writing. However, this core feature in the making of anthropological knowledge only became theorized and widely discussed in the 1980s and 1990s when an interdisciplinary intellectual movement with many facets and influences intensively assessed all aspects of the culture concept. Distinctive forms of reflexive thinking, analysis, and writing in anthropology have become canonical. This article reviews intellectual roots of this turn, its period of incorporation, and how it is manifested in contemporary anthropological research.

Essentially the capacity of a system of signification to turn back on itself, reflexivity, is the specific modality that an important critique of anthropological method and knowledge took in the 1980s. Reflexive inquiry has long been a potential in the social sciences. It experienced elaborate development in the United States as a result of the intersection of the influence of hermeneutical approaches and a sustained atmosphere of critique following the Vietnam War. Inherent aspects of ethnography were called into question by anthropologists themselves under the influence of trends of critical theory in literary studies and in interdisciplinary movements such as feminism and postmodernism, for which reflexivity was a key technique. The consequences for the process of inquiry in anthropology, represented by fieldwork and the genres of writing from it, have been far reaching and enduring. Reflexive practices are now mainstream in anthropology, and how they have worked their way into the changing conditions and subjects of contemporary ethnography is considered.

Critiques of the social sciences as practiced in the United States emerged in the 1980s in which reflexivity became a keyword, standing for both the means of the critiques and the form that alternative practices might take. The consequences for disciplinary practices of reflexivity as means of critique and alternative form of inquiry were nowhere as great among the social sciences as in social and cultural anthropology.

According to one of the early statements in this critical trend, reflexivity is "… the capacity of any system of signification to turn back upon itself, to make itself its own object by referring to itself: subject and object fuse" (Myerhoff and Ruby, 1982). Myerhoff and Ruby go on to stress that "significant distinctions exist between reflexiveness and related attitudes such as self-regard, self-absorption, solipsism, self-reference, self-consciousness, and autobiography. Reflexiveness does not leave the subject lost in its own concerns; it pulls one toward the other and away from isolated attentiveness toward oneself."

Reflexivity as a practice in the social sciences is, thus, both a distinctive mode of thinking and a strategy of writing that concerns itself with the process of inquiry as an integral part of the claims to knowledge that the inquiry might produce. As a concept, it is related to the idea of feedback in cybernetic models, of metacommunication, and of such functions as deixis and indexicality inherent in the faculty of language use. However, it is the more ideological uses of reflexivity in debates about the revision of anthropology's distinctive methods of fieldwork and ethnography that are of concern here. Debates about the role and purpose of reflexivity in the process of research as well as in the changing form of the ethnographic text became the major specifiable way of assessing the impact upon anthropology of the broader intellectual movement of the 1970s and 1980s known loosely as postmodernism.

In the broad sweep of European philosophy, reflexivity as a category of interest in social theory begins with Kant's distinction between analysis and an analytic in which an analytic is the kind of inquiry where the subject of inquiry is also the object of inquiry. One genealogical stream from this originary idea of reflexive inquiry leads through Hegel to phenomenology and eventually to Heidegger and existentialism in France. The other, and for us, more relevant genealogical stream leads to hermeneutics in the work of Hans-Georg Gadamer and Paul Ricoeur by way of the neo-Kantian writings of Dilthey and the work of Max Weber, in which reflexivity, while implicit, is a strong element of his methodological considerations. In the work of Gadamer and Ricoeur, reflexivity becomes an explicit and crucial intellectual operation in the activity of interpretation whereby the individual ethical consciousness expands reflectively through encounters with the foreign or the different. Thus, while long a potential existing in a sort of minor key to the predominant positivist tendency of social theory that oversaw the post–World War II expansion of sociology and anthropology in the United States, philosophical works of hermeneutics, in which the operation of reflexivity was highlighted, only developed explicitly a strong appeal among sociologists and anthropologists from the early 1980s onward.

Of all of the social sciences, the importance of reflexivity as a style of inquiry has been most natural to precisely those methods of anthropology that have distinguished it as a discipline. Pioneered by Bronislaw Malinowski and Franz Boas, the pursuit of fieldwork investigation through long-term participant observation, working directly in native languages, and the constant interpretation and translation of behaviors and speech encountered on a daily basis, inherently involves on the part of the investigator a keen consciousness of oneself and one's relations with specific others as the medium of all claims to knowledge from this research practice.

For a long time, anthropologists only came to terms with the complexities and problems of this distinctive form of knowledge production informally as a pastime of professional culture and folklore, as something to be communicated between mentors and students. It was only at the end of the 1960s, and then again, and more definitively in the 1980s, that anthropologists examined and developed explicitly the varieties of meanings and implications of reflexivity as a major style of knowledge production for the future practice of their discipline.

Since the 1980s, reflexivity has become a 'keyword' indicating both a self-conscious, mainstream style of work in anthropology and part of its own enduring disciplinary politics of knowledge. Here, it is important to note that reflexivity has only served as such a central category, standing in turn for the most concrete aspect of the controversial impact of postmodernism on anthropological practice, in the recent evolution of the discipline in the United States. It has been discussed and debated from the 1980s on in other anthropological establishments around the world, but mainly through the stimulus of the prestige and diffusion of trends in United States anthropology.

Reflexivity in Two Moments in the Critique of Anthropology

During the late 1960s, US anthropologists became preoccupied openly with a long simmering critique of their discipline. This critique had theoretical and methodological dimensions, but it was primarily political in nature, stimulated by the ferment of domestic resistance to the Vietnam War, renewed discussions of anthropology's historic development within the expansion of European colonialisms, and the interest in new work in Marxist theory. At that time as well, Geertz was developing a broad and deep theoretical foundation for cultural anthropology in hermeneutic philosophy, work that was eventually to serve as both the primary foil and influence for later discussions of reflexivity in anthropological method. (See Geertz, 1968, for his early position on reflexivity in fieldwork.) But in the *de facto* reflexive attempt to undertake a critical anthropology of anthropology in the politicized atmosphere of the 1960s, the issue of reflexivity itself as the major dynamic of what it was to practice critical analysis was little addressed. An important exception is the paper by Scholte (1969), which summarized this period of critique. Important as a figure who introduced currents of European social theory into US anthropology, Scholte foreshadowed what sort of theoretical work and changes in practice would be necessary to transform anthropology into a discipline with a sustained critical purpose beyond that moment of heightened political critique.

In the interval between the two periods of internal disciplinary critique, perhaps the most important work that served as the raw material on which the eventual surfacing of explicit considerations of reflexivity in anthropology depended was the burgeoning of a literature on fieldwork experience, written alongside the production of more formal ethnographies from which such reflections about the process of inquiry were largely absent. This literature, fueled by the publication of Malinowski's diaries in 1967, incorporated the spirit of self-critique of the late 1960s and was produced by anthropologists who were then students and young professors. There emerged a more theoretical strain of this literature in which the reflexive character of fieldwork became the major preoccupation (e.g., Rabinow, 1977) and that led eventually to experiments with the form of the ethnography itself (e.g., Crapanzano, 1980). These works, combined with an interdisciplinary movement, variously characterized as postmodernism and poststructuralism and led by scholars of literature who were experiencing their own disciplinary crisis, stimulated the theoretically deeper, more wide ranging, and sustained internal critique of anthropology of the 1980s.

Incorporating all the dimensions of the earlier critique, the 1980s critique primarily examined the central practices of the discipline, especially in its character as a hermeneutic enterprise, a view for which Geertz had laid the foundation. In particular, it did so by a focus on the rhetoric and forms of the signature textual product of anthropology, the ethnography. (See Clifford and Marcus, 1986; the volume that has stood for this critique in the way that the Hymes volume did for the earlier one.) This critique was, thus, the efflorescence of a comprehensive discussion of all the issues relating to reflexivity that had long been so essential to the practice of anthropology. Influenced by the circulation of much more diverse and sophisticated theoretical resources, anthropologists looked with an unprecedented intensity and thoroughness at the relationships in their work between reflexive modes of knowing, critical and ethical awareness, the political contexts of inquiry, and alternative possibilities for practice.

The basic act of reflexivity that initiated this critique were the probing discussions of the relationships of anthropologists to informants – of the self to other – and the dependence of the production of anthropological knowledge on these relationships, which had so often been effaced in the ways that ethnographies had in fact been written. Evoking alternative modes of representing others, questioning the act of representation itself, suggesting the ways ethnographic knowledge emerges from collaboration and dialogue, and probing the political conditions that have inhibited such possibilities, this moment of critique served both to stimulate degrees of experiment with the ethnographic form and to encourage ramifying discussions about the critical purpose of anthropological analysis (e.g., Marcus and Fischer, 1999). This undertaking was itself an umbrella act of reflexivity, and reflexive practice became the common frame for thinking about past ethnographies, future possibilities, and the form and purpose of anthropological knowledge itself. This field of discussion was highly contested: some felt that the critique by its nature was too hermetic, too literary, and not sufficiently committed to anthropology's study of social struggles in the contemporary world; some thought the attention to reflexive issues was an aesthetic distraction and a major blow to the production of objective knowledge that could be shared by a scholarly community and on which disciplinary progress depended; and contrastingly, for some, the kinds and levels of reflexivity encouraged by the critique were neither reflexive nor critical enough, leading to a spiraling array of discussions about insufficiencies and exclusions that had even more ideal reflexive practice in view.

The immediate effects of this period of critique were the changes in the ways that ethnographies were both written and discussed. But while the critique was developed through attention to texts and the way that anthropologists rhetorically established authority for them, the larger stake was the effort finally to justify them theoretically and ethically and expand anthropology as a critically reflexive field of inquiry. There can be little doubt that this much has been established as at least a long-term mainstream tendency in the discipline. This tendency has placed anthropology in much closer relation to such parallel interdisciplinary fields, themselves rooted in varieties of reflexive inquiry, as media studies, feminist studies, postcolonial studies, and most broadly, cultural studies, than to its historic partners in the other social sciences.

The Incorporation of Reflexivity in the Mainstream of Anthropological Research

Discussions about reflexivity, or at least the evaluation of ethnographic claims to knowledge in terms of the specific conditions and relations of inquiry that produced them from fieldwork, are not only highly visible and commonplace in anthropological discourse of the 1990s, they are *de rigueur*. Further, some form and degree of reflexive commentary is worked prominently into virtually every ethnography written these days. If not enacted in experimental text design, there is the presumption that all ethnography is produced collaboratively, and there are far richer and more probing discussions than ever before about the kinds of contexts that influence ethnographic representations of subjects and shape arguments from ethnographic data (see Marcus, 1994). Concern for reflexivity has had a special appeal for ethnographic filmmakers, and some of the most cogent writing on the importance of reflexivity in the representation of other forms of life have come from this arena (e.g., MacDougall, 1998). Current productions of ethnographic film and media demonstrate most clearly that the practice of reflexivity crucially redefines and adapts the classic conditions of ethnographic inquiry to new conditions of fieldwork where anthropological research projects must negotiate different identities and roles in relation to the highly articulated projects of their subjects in the overlapping contexts of a globally interconnected world.

Variant Ideologies in the Practice and Form of Reflexivity

In sociology, discussion of reflexivity has tended to be integrated formally as a methodological tool or technique (e.g., see Bourdieu, 1990), limiting its ability to affect fundamentally the forms and purposes of sociological research. In anthropology, the outcome has been quite different, generating a number of changes in the ways that ethnographies are written and fieldwork is conceived. This in turn has obviously had considerable implications for changes in both the form and content of the knowledge that anthropology's core research process generates.

In engagement with the terms of the 'writing culture' critique of the 1980s, the largest body of literature stimulated explicitly by reflexive inquiry examines in great detail the self–other relation in classic conditions and specific sites of fieldwork. While some have characterized this literature as narcissistic or merely self quests, in its most accomplished examples (e.g., Behar et al., 1995; Reed-Danahay, 1997; Taylor, 1999; Tsing, 1993), it has addressed cogently issues of contemporary changes in concepts of self, personhood, and identity among many of the peoples who had been the subject of study by previous generations of ethnographers. At the microlevel of fieldwork, it has also clarified aspects of the history of anthropology as an academic enterprise and in relation to the broad range of effects that inquiry itself has on the peoples and subjects studied (e.g., Rosaldo, 1989). While somewhat unruly and less governed by genre rules of form in social science writing, this literature has, in sum, been very useful in deepening and critiquing the complexities of constructs of subjectivity and otherness within their conventional usages in Western intellectual discourse – a long-term, continuing objective of anthropology as a discipline. It has also probed critically ethnographers' positions in relation to initial objects of study so as to transform the objects in novel ways and reconfigure the compass of research in response to radical contemporary changes in both the worlds of the academic and who is identified as subjects of study.

There has also been a strain of reflexive inquiry in anthropology for which reflexivity has been more distinctly a means by which to define an object of study or to circumscribe new temporal and spatial boundaries for a fieldwork project (Marcus, 1998). Key to these works is clarity of the positioning or location of ethnographic inquiry, which reflexivity enables, in relation to other historic and geographical agents in the same social field. Reflexivity as positioning not only serves the creation of new forms of objectivity in anthropology, sensitive to the issues of critique that discussions of reflexivity have raised, but redefines both the scope of ethnography and its arguments. In these works, the limits and reach of once very locally focused ethnographic arguments expand in unpredictable and intriguing ways (for a now classic experiment of this sort, see Taussig, 1987; for more recent examples, see Martin, 1994; Fortun, 2000).

Finally, there is the presence of reflexivity in ethnography because of the evolution of certain realities on the ground over the course of career-long scholarly involvements with certain peoples and places. In recent decades, literally self-conscious cultural awareness has increased markedly and even been mobilized politically in many locales and regions such that the conditions of ethnographic research require a rethinking and reorientation toward one's subjects, now organized into social movements, nongovernmental organizations, and other groups involved in objectifying and representing themselves. Here, reflexive inquiry is the means to a complex and necessary politics of research that not only shapes fieldwork but makes its continuation possible at all (see Warren, 1999; for an exemplar of this type of increasing variant of reflexive inquiry).

Reflexive Modernization and Reflexivity in the Changing Conditions of Anthropological Fieldwork

Broader changes in contemporary social conditions worldwide that stimulate the trend of reflexive inquiry in anthropology is encompassed in the concept of reflexive modernization (Beck et al., 1994), a development in social theory of the 1990s

that responds to the postulation of a present era of post-modernity by trying to specify the characteristics of such an era for the pursuit of empirical inquiry. This construct proposes that the modernity characteristic of industrial society is succeeded by a modernity that involves living with irreducible contingency, living in a more complex and less controllable world. Most importantly, reflexivity as a self-monitoring process on the level of both institutions and individual persons becomes not only a pervasive aspect of society, but also a key focus of social thought itself.

This version of social theory suggests for the proliferation of styles of reflexive inquiry in anthropology that these are not driven only as a result of the internal critique of anthropology, as a seminal countertrend to a preceding era of positivist tendencies, but as a more generally shared condition with the societies and cultures that anthropology makes its subjects of study. This suggestion in turn has a potentially profound and enduring effect on the research protocols of anthropology in recognizing certain affinities and identifications between the reflexive predicaments of ethnographers and those whom they study. Reflexivity is relevant not because it provides truer or more powerful explanatory models with which anthropologists can treat social facts among their subjects, but rather because reflexivity is also practiced differentially 'out there' on a widespread basis (see Marcus, 1999). This fact suggests the breaking of the frame of conventional scholarly work altogether, at least in the anthropological tradition, rather than the demise and replacement of specific concepts and characteristics of this academic frame. Thus, reflexivity is no longer only a moment in the critique of disciplines but becomes more generally the object and medium of social and cultural analysis as well.

Reflexivity into the 2000s

The legacies of the 'reflexive turn' begun in the 1980s, first with attention to the way ethnographies were produced and written, and then in the emergence of a vibrant theoretical apparatus about how to constitute subjects as the foci of contemporary anthropological research, are alive and well into the first and now second decade of the new century. They indeed have become canonical in the methods of ethnographic inquiry and in producing descriptive and analytic results from them. This is true, even in the burgeoning application of ethnographic methods to the study of virtual worlds (Boellstorff et al., 2012).

If there has been a different conceptual twist, or new thinking about reflexivity, it has accompanied a more general shift in anthropologists' interests toward ontological questions, more than epistemological ones. The latter evoke the essence of reflexive practices. These address questions of knowing, experience, meaning, and the relationships between the anthropologist as observing/interpreting agent and his or her subjects as the main focus of inquiry. Ontological questions are evoked and stimulated by the changing objects and environments or circumstances in which ethnographic fieldwork is situated anywhere today. They concern the analysis and description of the emergence of new forms, organizations, processes, and practices. Descriptive and analytic attention to materiality, techniques, invention, and new patterns of relations and transaction takes precedence over symbolic or hermeneutic analysis.

New technologies, global projects, environmental change, disasters, infrastructures, emphases on material conditions of life, and the new levels of awareness and entanglements that these changing conditions of planetary life cause everywhere, all require new thinking about how to situate anthropological research as fieldwork, and how to negotiate conditions of sustained inquiry. For anthropological research projects, this embedding of fieldwork in complex global projects requires unprecedented levels and degrees of collaboration and alliance with assemblages (Ong and Collier, 2005) of experts, activists, and stakeholders, and stimulate new adaptations of established tendencies in conducting fieldwork. Anthropologists of course remain interested in the life worlds of subjects with which they reflexively engage, but in order to even define subjects in this way today they have to conceive of working on, and within, new projects, structures, and organizations of unprecedented complexity and technical constitution, along with a politics of doing research that requires negotiations of traditional categories (such as culture, the human, kinship, or even ethnography itself), which have defined the specialized terms of disciplinary discussion within anthropology itself.

This increased curiosity about the ontology of new objects of study in the world, and being immersed as fieldworkers within them as assemblages of relations in systems of distributed knowledge, requires a kind of modified or morphed reflexive posture. In confronting this renewed trend of working within complex systems (of governance, of markets, of finance, of technoscience), anthropologists have not for the most part returned to the techniques of formal modeling characteristic of the other social sciences, but rather have continued to adapt theoretical innovations to the still largely qualitative nature of ethnographic research. The most influential conceptual paradigm emerging at the turn of the century, supporting this shift toward the ontological in anthropology has been actor–network theory, associated with the work of Bruno Latour (2005). While problems of reflexivity are discernable in this paradigm, they have not been explicitly addressed much by its major proponents.

How then to think about the shift from, or parallel to, reflexivity, when anthropologists become immersed as fieldworkers in complex assemblages of relations, tied to emergent changes and events, and thus return to an interest in describing systems, structures, and macroscale events? In the author's view, the most cogent expression of what the discussion of the concern with reflexivity becomes in anthropology's new entanglements, with an accented ontological interest, in complex systems and distributed knowledge assemblages is Kim Fortun's formulation (2000), in her study of the environmental justice movement following the Bhopal disaster. She tracks her conceptual shift from a stance of reflexivity to recursivity (2000: p. 23):

> Reflexivity calls for the ethnographer to position herself. Recursivity positions her within processes she affects without controlling, within competing calls for response. Reflexivity asks what constitutes the ethnographer as a speaking subject. Recursivity asks what interrupts her and demands a reply. Thinking in terms of recursivity is a way to hold ethnography responsible for advocacy. Attention to recursivity foregrounds how every articulation—whether ethnographic or in direct advocacy—operates on previous articulations, inserting every move and every word within multiple discourses and worlds…

One can see this variant of reflexivity, as recursivity, operating methodologically and analytically in contemporary anthropological research within its other major thematic: that is, to operate in, and speak to, public spheres, to be engaged, and even activist at the same time that it produces research that is empirical and achieves scholarly standards. The intimate, microscale settings of fieldwork by which reflexivity was intersubjectively theorized in the 1980s and 1990s now become a discussion about the ethical and normative commitments of anthropological knowledge, and its accountabilities as such, in relation to specific publics, institutions, and global projects as ethnographers move recursively in their circuits of inquiry, as evoked by Fortun. The original idea of methodological reflexivity in ethnographic inquiry thus now encourages anthropologists to shape and present their findings in relation to a larger community of reception and debate. Beyond a kind of rhetoric of desire and purpose, any fulfillment of this goal of engaged research would entail specific arguments and analyses from the recursions of fieldwork that link anthropologists with subjects through their movements within complex systems or assemblages. Recursivity is thus less a situating of fieldwork practices in relation to subjects, which reflexive practices classically have done, but provide a compass for movement through an unknown terrain of not just places, locales, and situated communities, but concepts, programs, discourses, values, and the communities or publics that produce them. This is what or more, or different, about what reflexivity has become in anthropological research moving into the twenty-first century.

Abstract

This article looks at the history, varieties, influences on, and criticisms of reflexivity in science and technology studies (STS). It deals with the epistemic, aesthetic, practical, and political aspects of reflexivity in this context. First, the meanings of 'reflexivity,' as this term has been understood in STS, are set out. A brief history of the varieties of reflexive concerns in this field is presented, from Bloor's explicit, yet limited, endorsement, to the full-blooded treatments of 'the reflexivists' (Mulkay, Woolgar, Ashmore) and beyond. Criticisms of reflexive writing from within STS (especially from Collins and Latour) are dealt with and responded to. A consideration of the internal role and status of reflexive work in STS and an assessment of the current state and future prospects of reflexivity are undertaken.

Introduction

"Considerations of reflexivity have salience in diverse intellectual practices and traditions: literature, philosophical logic, the visual arts, cybernetics, as well as social theory and sociology. Indeed, it is an issue with potential relevance for all modes of representational and performative practice. In the most general terms, considered as a feature or style of inquiry, reflexivity is a concept that expresses a concern to turn 'subject' into 'object,' to turn the activity of inquiry into a topic for (its own) inquiry. To 'be reflexive' is to bring the process of doing an activity into the purview of that activity as a feature of it. Thus, it implies a certain self-consciousness, and a certain paradoxical, even Zen-like, mode of operation: bootstrapping; attempting to see the flashlight that illuminates the scene as a part of the scene it illuminates; taking account of this moment as one writes of 'this moment.' This article details the ways in which reflexivity has featured in science and technology studies (STS), and speculates on the current and future status of reflexive study in STS.

Alternative Introduction

This heading is not to declare, exactly, that there is anything 'wrong' with that first introductory paragraph. It does the job, and it does it correctly; that is, in accord with the 'Instructions for Manuscript Preparation' for this encyclopedia. It is just that in doing 'just that,' it is unable to acknowledge the conditions under which it does so. Thus, it leaves all those things out of (its) account; which is normal, and normally unobjectionable. Perhaps no other article in this *encyclopedia* makes any reference to such things, preferring instead, perfectly 'obviously,' to concentrate on the primary task of speaking authoritatively (and, importantly, briefly) about its topic. Thus, the conditions of production of these particular texts are constructed as irrelevancies for, and obstacles to, the proper work. Social science inquiry that focuses on conditions of production has always acted (intentionally or not) to 'make trouble' of this kind: Marxist economics for capitalism; sociology of education for teaching; STS for science and technology. Reflexivity adds a twist to this dynamic: in collapsing the external/internal, outsider/insider, on/in relation, the source of trouble, being as much 'here' as it is 'there,' is no longer clearly located or easily attacked. This, then, is the primary role for reflexive inquiry: to make things difficult; to enrich the process of inquiry; to go round and round in circles; to fill out the picture; to frustrate all action; to act authentically and without self-contradiction; to change the subject.

Reflexivity as a Problem

In STS, the impetus for explicitly reflexive studies has been felt most strongly in the important subfield of STS known as the sociology of scientific knowledge (SSK). Here, the reflexive tie between its subject (knowledge about scientific knowledge) and its object (scientific knowledge) is very marked. That is, SSK exhibits a strong 'X of X' structure. Because of this, and because SSK's epistemology is explicitly relativist, reflexivity in SSK has a 'bite' akin to classic philosophical skepticism.

Extremely crudely, and for illustrative purposes only, SSK's relativism with respect to scientific knowledge can be, and indeed has been, taken as equivalent to a statement of this kind: "Scientific knowledge does not constitute truth because it is socially constructed." Read this way, SSK then becomes vulnerable to the standard antirelativist critique, the argument from self-refutation: "If this statement is asserted as a (scientific) truth, then it suffers from performative self-contradiction, and thus refutes itself" (see, for example, Hollis and Lukes, 1982). Note that the self-refutation argument uses reflexivity: it is through the process of turning its target onto itself that the demonstration of self-refutation is effected.

This is indeed one of the commonest modes in which reflexivity operates: as a weapon in the agonistic game of criticism. Thus, for those threatened with attack-by-reflexivity, it becomes a source of vulnerability to be abjured and defended against. Reflexivity becomes a 'problem' to be 'managed.' The various ways in which practitioners of SSK have done this, have made up one of the preoccupations of 'reflexivist' studies (see Section Relativist Consistency, Radical Reflexivity: The Reflexivists).

Logical Consistency: Bloor's Strong Program

David Bloor's *Knowledge and Social Imagery* (1991) is one of the earliest texts to set out the elements of what has become known as SSK. It contains an endorsement of reflexivity as the fourth and last of the 'tenets' for the "strong program in the sociology of knowledge": "In principle [the strong program's] patterns of explanation would have to be applicable to sociology itself. Like the requirement of symmetry, this is a response to the need to seek general explanations. It is an obvious requirement of principle because otherwise sociology would be a standing refutation of its own theories" (Bloor, 1991: p. 7).

Here, Bloor's positive support for reflexivity is a matter of logical consistency and a creative way of managing the self-refutation charge. Rather than deny the reflexive applicability of the strong program, Bloor emphasizes it, secure in his understanding that the socially constructed character of all knowledge, including his own, does not count against its validity. Bloor's reflexivity, however, remains at this 'in principle' level. His negative attitude toward any empirical instantiation of his reflexive programmatics is documented in a text that claims to be precisely that (Ashmore, 1989). Thus for Bloor (as well as for his former 'Edinburgh school' colleague Barry Barnes (1974), Epilogue), reflexivity is an argument used to defend a position; it is certainly not a practice.

Harry Collins: Special Relativism and the Ban on Reflexivity

Not so for, for example, Harry Collins (1985), perhaps the most influential writer through the heyday of SSK (*c.*1975–90). Collins's doctrine of 'special relativism' separates the natural world from the social world and the distinctive tasks and 'natural attitudes' of the natural scientist from those of the social scientist. The sociologist of scientific knowledge should treat the natural world as socially constructed, while treating the social world as 'real' and a source of sound data. However, this sense of 'realism' is taken from a reading of how natural scientists act toward their realm of inquiry, namely, the natural world. In effect, what Collins is doing here is to deny, for purposes of the conduct of research, the practical relevance of the purported reflexive similarity between subject and object in SSK. The result is the short-circuiting of attempts to apply Collins' conclusions about, for example, the replication of experiments to those conclusions themselves (nevertheless, see Mulkay, 1985: Chapters 4 and 5; Ashmore, 1989: Chapter 4). In short, Collins' 'management strategy' for reflexivity is to ban it altogether. This radical solution to the problem of reflexivity has laid Collins open to charges of inconsistency from both wings of the 'realist–relativist' continuum. The recommended moves for repairing this perceived inconsistency differ, however, with the 'realist' suggesting he abandon his problematic relativism about nature, and the 'more-radical-relativist' proposing the dropping of his social realism (*see* Technology, Social Construction of).

Relativist Consistency, Radical Reflexivity: The Reflexivists

In the late 1980s, a small number of 'full-blown' reflexive texts were published (Ashmore, 1989; Mulkay, 1985; Woolgar, 1988). This group of writers became known as 'reflexivists.' Ashmore's *The Reflexive Thesis* is an SSK study of SSK, a general exploration of reflexivity, and an experiment in 'new literary forms.' Mulkay's *The Word and the World* is a series of 'explorations in the form of sociological analysis' that draws upon analyses of biochemists' discourse. Woolgar's *Knowledge and Reflexivity* is a collection of papers from a small group of regular contributors (including Ashmore, Mulkay, and Woolgar) to the Discourse and Reflexivity Workshops held in the United Kingdom in the early 1980s. What links all these texts together, apart from their authors' close socio-cognitive relations to one another, is the common attempt to treat reflexivity less as a problem and more as an opportunity; an opportunity, even, for celebration. What happens when one stops evading reflexivity, when one looks 'the monster' in the eye, when one gives it a place at the heart of the research process? Self-destruction? Massive irrelevance? Third apocalyptic simile?

Bruno Latour's contribution to *Knowledge and Reflexivity* (Latour, 1988) is an exception. Latour argues that the 'meta-reflexive' writing strategies of the reflexivists provide a solution to a false problem: namely, the imagined naiveté of readers who believe too much and too easily. On the contrary, the real problem that (scientific, factual) writers have, is to be believed, or indeed, read at all. Latour further claims that the reflexivists are searching, despite their own gestures at weakening their own authorial privilege, for a final meta-level that leaves no remainder and from which vantage point, everything can be taken into (their) account. As an antidote to such impossible ambitions, Latour recommends a strategy of 'infra-reflexivity': just to tell stories, drawing upon the richness and variety of all the 'ordinary' resources available. Latour's *Aramis* (1992, 1996) – despite its appearance as an experiment in 'new literary forms' – is, perhaps, an example.

Criticisms: Pitfalls and Pratfalls

Reflexivity gets you nowhere. It is not a useful thing to do and its results cannot be used. It is impractical. As an activity, it immobilizes you. It leads to idle navel-gazing and foolish self-absorption. It is 'all pots and pans and no pudding' (Bloor, cited in Ashmore, 1989: p. 20). Logically, it leads to the abyss of the infinite regress or the never-ending search for the perfect meta-level. Reflexivity is politically and morally irresponsible games playing, fiddling while Rome burns. It has no soul (to bare) and no wisdom (to distribute), just an overdose of clever–clever irony. It disables criticism by taking that role on for itself; in its attempt to play all the roles of the academic community at once, and all by itself, it betrays itself as deeply, and ironically, antisocial. Indeed, it appears to seek nothing from its readers but a kind of 'aesthetic' admiration marked by a knowing, smug, and boyish amusement.

However, for the larger STS community, reflexivity has had positive functions and effects. The reflexivist fulfills the important role of the jester at the court of STS. Moreover, the presence of reflexive work as part of the 'canon' of STS, acts as a corrective to a kind of methodological overconfidence resulting from the recent success of the field. Reflexivity

reminds us that the fundamental epistemic questions and quandaries that originally animated SSK are permanent features of the practice of 'inquiry into inquiry' epitomized by STS scholarship. The text that aspires to 'transparency,' that is, blithely unconcerned with the conditions of its own production, is now, at the very least, 'visible,' a member of a marked, rather than unmarked category.

The Current Situation"

Careful or instructed readers will notice that all of the above (starting in the first section, and running through the end of this section's heading) is 'in quotes,' which indicates that the quotation includes almost all of this article, up to 'this' point, as it appeared in the 2001 edition of this *encyclopedia* (Ashmore, 2001). So what, then, now, is the current 'Current Situation' – though not, unfortunately, the (post-publication, 2015 and beyond) current, but the compositional Now of late 2012?

New 'New Literary Forms'?

Though this author, clearly, is still given to playing minor textual games, are these still being played in STS in the post-reflexivist era? Though hardly prominent, and certainly not trumpeted as *new* 'new literary forms,' experimental texts do still appear. Latour's *Aramis* (1992, 1996) (see Section Relativist Consistency, Radical Reflexivity: The Reflexivists) is more a detective story than a conventional technography of the eponymous, failed, rapid-transport system that is its topic; a story that even features the Aramis system accounting for its own death. Mol's *The Body Multiple* (2002) sustains a double text throughout: on top, her ethnography of the disease of atherosclerosis, and on the bottom her relation of her 'relation to the literature' – see also Ashmore (2005) which attempts a pale salute to Mol's achievement.

Radical Reflexivity: Is It All Over Now?

A session at the 4S/EASST (Society for Social Studies of Science/European Association for the Study of Science and Technology) conference held in Vienna in 2000 bore the title now given to this section. Most effectively dramatizing the question, one paper in that session, presented as a letter to its speaker, Steve Woolgar, from the seemingly-apocryphal 'Brian Peabody PhD OBE FREng' raised the question (a question raised before, according to the letter, by one of Woolgar's students) 'What happened?': "Looking for the standard indicators of the success of the field, you might ask where are the new journals of reflexivity, the international association of radical reflexivity (IARR), the annual conferences (Reflex, 2000), the newly established Chairs in Reflexivity and so on" (Woolgar, 2000: p. 3). Peabody/Woolgar then goes on to suggest that reflexivists would be bound to be skeptical of the value and desirability of such indicators, and thus, precisely because of their absence, "… reflexivity has succeeded spectacularly. Reflexivity is a success because it has argued itself out of a job" (Woolgar, 2000: p. 3). Rappert (2007), which includes a commentary on the Woolgar/Peabody 'personal correspondence' of 2000, treats the 'failure' of the reflexivist program as his main example of the difficulties involved in making constructivist generalizations. (Interestingly, Rappert's paper, despite its negative conclusions about the program that introduced such devices, uses an unconventional double text – see Section New 'New Literary Forms'?) Knuuttila (2002) conducts a similar postmortem on STS reflexivism, concluding that "[i]n retrospect, it seems fair to say that radical reflexivity of STS stumbled against its own impossibility" (paragraph 28). Pels (2000) is less apocalyptic in his rejection of reflexivism, which he understands as a matter of the infinite ascent of meta-levels, with no (logical) endpoint. He recommends, both as an alternative to this endless spiral and to the flatness of classical realism, 'one step up,' no more and no less. In this, as he acknowledges, he is close to Latour's (1988) 'infra-reflexivity' (see Section Relativist Consistency, Radical Reflexivity: The Reflexivists).

Social Science's Ubiquitous Reflexivities

Meanwhile, elsewhere, 'reflexive' has, over the last 20 years or so, become a highly desirable attribute of any ethnographic, qualitative study throughout the social sciences (May, 1999). What is meant by this term, though, when lauded so positively, is rarely anything like its understanding in STS reflexivism. Most often, a claim that an author (or text, or work of research) is reflexive means that some notice is taken of the involvement of the 'subject' in the working up of the 'object.' (A representative discussion is Finlay, 2002.) The extent and character of this involvement, as Lynch's (2000) comprehensive typology makes clear, is highly variable, but is often satisfied with an autobiographical gesture or two. As an indicator of the near-ubiquity of reflexive claims in qualitative social science, the online journal *Forum: Qualitative Research* published two special issues on 'Subjectivity and Reflexivity in Qualitative Research' (issue 3(3) in 2002 and 4(2) in 2003) comprising a total of 32 articles. Lynch's (2000) effort is rare enough, these days, in mounting an argument, to quote the title, 'Against Reflexivity as an Academic Virtue and Source of Privileged Knowledge.' As a precursor to mounting this argument he catalogs the reflexivities into six major types: 1. mechanical (with three variants); 2. substantive (two variants); 3. methodological (four variants); 4. meta-theoretical (three variants); 5. interpretative (two variants; 5b being the 'radical reflexivity' associated with STS reflexivism); 6. ethnomethodological (just the one). Lynch's preference is for type 6, as, being a ubiquitous and unavoidable feature of the social world, ethnomethodological reflexivity cannot be a matter of claims-making, and thus the potential gaining of virtue or privilege, at all.

The term 'reflexivity' has also become prominent in social theory, particularly in the influential thesis of 'reflexive modernization' put forward by Beck et al. (1994) – Lynch's (2000) type 2a: substantive/systemic – where 'our' modernity is characterized as pervaded by reflexive monitoring of its own processes in the form of cost–benefit and risk analyses, opinion-polling, and so forth. Another well-known social-theoretic source of reflexivity occurs in and as the work of Bourdieu (Bourdieu, 2001, 2004, 2008; Bourdieu and

Wacquant, 1992; see Maton, 2003 for a general discussion). Bourdieu's 'hyperobjectivist' form of reflexivity (type 4c) – entailing the scientific objectivation of the subject of objectivation – incurs the wrath of Lynch (2000: pp. 30–31); but then, at the end of his life, Bourdieu (2001, 2004) directed his own wrath at 'the new sociology of science' (SSK/STS), a move lovingly described by Mialet (2003). A later posthumous work (2008) is reviewed by Gingras (2010) as demonstrating the superiority of Bourdieu's 'sociological' reflexivity over the 'textual' version homegrown in STS "that rapidly led to an impasse" (Gingras, 2010: p. 619).

STS' Topical Extensions

It has been a long time since STS was mainly SSK together with ANT (actor network theory); indeed this couple largely ceased to cohabit following the polemics published in Pickering (1992). STS has become extraordinarily diverse, topically, conceptually, institutionally, and nationally. Though the acronym STS seems to specify a single (double) topic, that of science and technology, its topics have now expanded into a whole range of what Lynch (1993) has called 'epistopics': law and legal deliberations, politics and policy, engineering and design, medicine and health care, finance and markets; and all the hybridities performed when 'science' and/or 'technology' (technoscience) meet (these and) other institutions and practices – particularly as heterogeneous assemblages forming around public 'matters of concern' as opposed to the private laboratory-based production of 'matters of fact' (Latour, 2004; Latour and Weibel, 2005). Where, if anywhere, is the place of reflexivity in this STS?

The varieties of reflexivities (see section Social Science's Ubiquitous Reflexivities) have made themselves felt in STS, as they have elsewhere. A recent special issue of *Science as Culture* (Cohen and Galusky, 2010) is dedicated to reflexivity conceived as how personal narrative and experience can lead to STS-relevant insights. A rather different sense of the term is present in Wynne's normative call for greater 'institutional reflexivity' (Wynne, 1993); an emphasis that applies the (positive) attribute of reflexivity, not to the STS researcher, but to the researched; that is, to scientific institutions that tend to suffer from a self-awareness deficit. And what of the emphasis of the 1980s reflexivists? It can sometimes seem as if this never existed. Collyer (2011: p. 316) argues that "despite its potential, theorising within the sociology of science and technology is hampered by insufficient attention to … the concept and practice of reflexivity"! An endangered species, evidently (see Section Radical Reflexivity: Is It All Over Now?) but not yet quite dead, though largely confined to a counterintuitive corner of the STS universe – that of business schools and marketing research – courtesy of the Final Reflexivist, Steve Woolgar's elevation to Professor of Marketing at Säid Business School, Oxford University (Neyland and Simakova, 2009).

Thus…

… though the career of 'reflexivity' has never been healthier, it has, in the STS context, lost much of its radicalism, bite, and distinctiveness, much as Pollner (1991) complained, years ago, in the case of ethnomethodology. Whether this, Dear Reader, is any cause for concern, is, as always, a matter in you to decide.

Reformation and Confessionalization

Ute Lotz-Heumann, University of Arizona, Tucson, AZ, USA

Abstract

This article provides an overview of the historiography and the major historical developments of the Protestant Reformation, Catholic reform, and confessionalization in sixteenth- and seventeenth-century Germany and Europe. In the first part of this article, the historiography of the Reformation and the confessional age is discussed, with particular emphasis on questions of periodization. In the second part, the major historical developments between the late Middle Ages and the middle of the seventeenth century in the German Empire as well as in Europe are summarized.

Historiography and Periodization

The era of the Reformation and Confessionalization encompasses roughly the period between 1500/1517 and 1650/1700, i.e., the first part of the early modern period (if one includes the Enlightenment in early modernity). But even this vague definition has been debated in historiography and there is by no means a consensus on the periodization of the Reformation and the confessional age.

Reformation and Counter-Reformation

In nineteenth-century German historiography, not least through the influence of Leopold von Ranke (Ranke, 1839–47), 'Reformation' and 'Counter-Reformation' ('*Gegenreformation*') were established as two distinct historical periods in the sixteenth century, with the Protestant Reformation occupying the earlier half and the Catholic Counter-Reformation the latter half. Building on earlier Protestant interpretations of the Reformation, Protestant Prussian historiography regarded the Reformation as a breakthrough to modernity, a German event that changed the course of world history by spreading values like rationality. This view was still reflected in the modified subtitle of the leading journal in the field, the *Archive for Reformation History*, after it became a German–United States collaboration in 1951: "international journal concerned with the history of the Reformation and its significance in world affairs" (ARG 42 (1951)). In contrast, 'Counter-Reformation' implied a mere reaction to the new Protestant movements of the early sixteenth century.

Over the course of the nineteenth and twentieth centuries, this view of the sixteenth century with its clear Protestant bias was much debated. With regard to Counter-Reformation, historians pointed to the fact that there were numerous Catholic reform movements during the late Middle Ages, which in turn made it clear that the Counter-Reformation was not only a reaction against Luther and other reformers, but an early modern 'Catholic Reformation' in its own right. This discussion culminated in Hubert Jedin's suggestion for a compromise term in 1946: 'Catholic reform and Counter-Reformation' (Jedin, 1999).

With regard to the Reformation as a marker of a new era and a breakthrough to modernity, twentieth-century scholars cast serious doubt on this conception. Ernst Troeltsch argued in 1906 that the 'Old Protestantism' ('*Altprotestantismus*') of Luther and the other reformers was deeply embedded in the Middle Ages and only the 'New Protestantism' ('*Neuprotestantismus*') of Protestant groups like Baptists and Spiritualists had brought about modernity (Troeltsch, 1906). Later historians emphasized long-term trends and comparatively stable structures in society and economy (for example, the social hierarchy or the household as the basic social and economic unit) which, in their view, minimized the significance of the religious upheavals of the sixteenth century for periodization. For example, the German-American historian Dietrich Gerhard suggested to replace the idea of a historical break around the year 1500, with the Protestant Reformation as the major component, with a period called 'Old Europe' lasting from the eleventh until the end of the eighteenth century (Gerhard, 1962).

Reformation and Confessionalization

Since the 1960s, and especially the 1980s, these discussions have continued, with new historiographical concepts throwing different lights on the question of periodization. In terms of the Reformation as an epochal break, Marxist historians in East Germany – taking Engel's interpretation of the German Peasants' War as a positive revolutionary event as their starting point – considered the Peasants' War with Thomas Müntzer as its leader and the radical Reformation an 'early bourgeois Revolution.' This interpretation of the Reformation largely ended with the fall of the Iron Curtain.

In contrast, it more and more became a consensus among historians in the West (albeit with some variation and different emphases) that the Reformation should be regarded as part of a longer period of change encompassing the late Middle Ages and beginning of the early modern period. Heiko A. Oberman described the Reformation as the culmination of a long, late medieval reform process which, however, did not culminate in the Lutheran, but in the western European, Calvinist Reformations (Oberman, 2001). Heinz Schilling has argued that the Reformation was part of a long-term challenge and response process lasting from the reforms of the late Middle Ages until the age of Confessionalization (Schilling, 1998). And in Berndt Hamm's model of 'normative centering,' the Reformation is seen as a theological break, but, overall, as part of a much broader process of centralization and concentration in all areas

 http://dx.doi.org/10.1016/B978-0-08-097086-8.62009-3

of late medieval and early modern life (politics, society, economy, the arts) (Hamm, 1993).

With regard to the relationship between Protestantism in the second half of the sixteenth century and the 'Counter-Reformation,' Ernst Walter Zeeden fundamentally changed the trajectory of historical research when he observed in 1958 that, during the second half of the sixteenth century, Catholicism, Lutheranism, and Calvinism each started to build a modern, clearly defined church, each of which centered on a specific confession of faith. He called this process 'confession building' ('Konfessionsbildung'), a neutral term which could be applied to all churches (Zeeden, 1958).

In the late 1970s and the early 1980s, two scholars of the next generation, Wolfgang Reinhard and Heinz Schilling, reinforced this historiographical change by developing the concept of 'confessionalization' (e.g., Schilling, 1986; Reinhard and Schilling, 1995). This paradigm dominated historiographical discussions for the next 25 years and resulted in a shift in research interests. While the historiography of the 1960s and 1970s had focused on the first half of the sixteenth century with a particular emphasis on the urban Reformation (e.g., Brady, 1978; Greyerz, 1980; Moeller, 1987), from the 1980s onward, historians shifted their attention to the second half of the sixteenth century and the early years of the seventeenth century.

The concept of confessionalization countered the negative and antimodern implications of the term 'Counter-Reformation' by replacing it with the idea that the confessional churches of the early modern period underwent parallel developments. As a result, Schilling and Reinhard suggested replacing the terms 'Lutheran orthodoxy,' 'Second Reformation' (for Calvinism), and 'Counter-Reformation' with the parallel terms 'Lutheran,' 'Calvinist,' or 'Catholic confessionalization' (Schilling, 1992: pp. 209–210). Nevertheless, the periodization of the era of confessionalization remains unclear. Heinz Schilling has developed a periodization of the process of confessionalization in the Empire between the Peace of Augsburg in 1555 and the Thirty Years' War (Schilling, 1992: pp. 216–232). Schilling sees four phases: first, a 'preparatory phase' starting in the late 1540s; second, the 'transition to confessional confrontation' in the 1570s, when all three churches acquired clear confessions of faith and began a process of boundary and identity building; third, the 'apogee of confessionalization' between the 1580s and 1620s, when the hardening of religious lines continued and was reinforced by political conflicts in the Empire, leading to the outbreak of the Thirty Years' War; and fourth, 'the end of confessionalization under the conditions of war and on the basis of the Peace of Westphalia' starting in the 1620s. In this phase, the devastation and suffering of the war led to the realization, resulting in the Peace of Westphalia, that compromise was the only realistic option.

The debate about the concept of confessionalization has led many scholars, especially those who work on Catholic areas, to doubt Heinz Schilling's periodization. Wolfgang Reinhard has extended the process of confessionalization much further, starting with the Augsburg Confession of 1530, the first Lutheran confession, and ending with the expulsion of the Salzburg Protestants in 1731–32 which was, according to Reinhard, the last confessionally motivated act of expulsion in the early modern Empire (Reinhard, 1995: p. 435). Others have argued that the thesis of parallel developments (and thus a periodization applying equally to all confessional churches) cannot stand, particularly in view of the fact that Baroque Catholicism continued to shape Catholic confessional identity and culture well into the eighteenth century.

Heinz Schilling and Wolfgang Reinhard understand the concept of confessionalization as a broadening of the concept of confession building, which was focused on religious history, into a paradigm of societal history. As a result, they regard confessionalization as a 'fundamental process of society' (Schilling, 1992: p. 209) in which all confessional churches, in close alliance with the early modern state, homogenized the population, intensified social disciplining, and solidified confessional, political, and cultural identities. They argue (in clear opposition to the earlier implications of the term 'Counter-Reformation') that all churches thereby underwent a (partially unintended) process of modernization, and that, rather than focusing on doctrinal differences as the older historiography did, the concept of confessionalization reveals the "functional similarities" (Schilling, 1992: p. 210) between the early modern confessional churches.

In this context, Wolfgang Reinhard has identified seven methods, or mechanisms, of confessionalization, used by church and state to try and establish confessional homogeneity (Reinhard, 1999: pp. 177–182). First, the definition of 'pure doctrine' in a confession of faith meant that a church was defined vis-à-vis other confessional churches. Second, these norms then needed to be imposed on the personnel of the church, for example, through confessional oaths. Third, church and state used the printing press for propaganda and tried to put in place a system of censorship. Fourth, by establishing educational institutions on all levels, church and state attempted to influence the younger generations. Fifth, through different measures of social control like visitations and church discipline, church and state aimed at creating a confessionally homogeneous population. Sixth, religious rituals were cultivated as markers of a confessional church, and participation was monitored so as to ensure the loyalty of the faithful. Seventh, Reinhard refers to the confessionalization of language, for example, the choice of first names in different confessions.

The concept of confessionalization resulted in an intense and long-lasting historiographical debate which started in the early 1980s and is still ongoing, although it has significantly lessened in intensity since the mid-2000s. This debate has focused on elements of the concept that many historians have regarded as too rigid and/or limiting. Above all, the concept of confessionalization has been described as a product of German societal history of the 1970s with its focus on modernization theory following Max Weber. Social and cultural historians have rejected the concept on the grounds that its claim that confessionalization had modernizing effects is teleological and that it does not do justice to the complexities of sixteenth- and seventeenth-century developments. In a similar vein, historians and church historians have criticized the concept for its emphasis on parallel developments in all major confessions. In their view, this detracts from the specific characteristics of each confessional church and reduces religion to its social and political functions.

Another major criticism of the concept pertains to its claim that confessionalization was a fundamental social process, affecting all areas of early modern life. There has been much debate on the question how deeply confessionalization reached into different areas and aspects of life with critics of the concept putting emphasis on its limitations, for example, with regard to changing popular religion on the one end of the social spectrum and the supraconfessional nature of the Humanist republic of letters on the other. Finally, the close relationship between confession building and state formation postulated by the concept of confessionalization has given rise to major discussions. In recent historiography, there is a consensus that Reinhard and Schilling have overemphasized the role of the state in the process of confessionalization, thereby describing it as a top-to-bottom process which does not take into account agency from below, various forms of resistance, and self-confessionalization.

Overall, the social history of the Reformation and confessional age, which – parallel to the debates about the concept of confessionalization – dominated the field in the later twentieth century and emphasized subjects like popular religion and gender (e.g., Scribner, 1981; Roper, 1989; Wiesner, 1993), has developed in the last 20 years into a new cultural history. On the one hand, this new cultural history is concerned with completely new questions, researching emotions, rituals, space, sound, and material culture in the religious movements and churches of the sixteenth and seventeenth centuries (e.g., Karant-Nunn, 1997, 2010; Spicer, 2012). In doing so, this new cultural history has moved beyond the issues that earlier generations of historians struggled with: The term 'Counter-Reformation' is now used as a completely neutral term without its previous negative connotations. The term 'Reformations' or 'age of Reformations' (in plural) is often employed to denote a period encompassing the Reformation and the confessional age. And historians analyze Protestantism and Catholicism 'on the ground' in the early modern period without currently discussing macrohistorical questions of modernization, state formation, or social control.

On the other hand, the 500th anniversary of the Lutheran Reformation in 2017 will not be without consequences for historical research. As this article goes to press, it is not yet clear how this will affect research on religion in the early modern period overall. However, two trends are already discernible: Research interests are clearly shifting back to the period of the early Reformation. And there seems to be a growing interest in the biographies of the central figures of the Reformation, above all, of course, Luther.

Religious, Social, and Political Structures and Developments in the Era of the Reformation and Confessionalization

Electoral Saxony, the territory where the Lutheran Reformation originated, was part of the Holy Roman Empire of the German Nation, a conglomerate of territories of different sizes and political power in central Europe. When the Wittenberg theology professor Martin Luther (1483–1546) published his 95 theses and other writings in an effort to reform the Church, his own fate and the fate of the evangelical movement were determined by the political makeup and developments in the German Empire and its territories. Soon, however, the Protestant Reformation, which could not be repressed in Germany, became a European phenomenon.

Other major reformers emerged, not least Huldrych Zwingli (1484–1531) in Zurich, who deeply influenced Reformed theology in Switzerland and upper Germany, and Jean Calvin (1509–64), the Genevan reformer, whose theology spread across wide swathes of Europe (France, the Netherlands, the German territories, the British Isles, and east central Europe). As a result, Protestant confessional churches were established all over central and northern Europe, each with a different doctrinal basis, ecclesiastical organization, and church–state relationship. At the same time (and only partially as a reaction to the Protestant Reformation), the Catholic Church underwent a fundamental process of reform. The Council of Trent (1545–63) defined the Catholic Church as a confessional church both in theology and church organization.

Basic Structures

The Reformation and the confessional age were characterized by a number of basic religious, social, and political structures that are important to recognize when analyzing the events and developments of the sixteenth and seventeenth centuries. First, it is essential to recognize that there existed in the early modern period a strong ideal of the unity of church and state. In the eyes of contemporaries, one state should have only one religion. As a result, rulers attempted to unify religion and politics and use religion as an instrument of state formation.

Second, this did of course not mean that rulers succeeded and achieved their ideal. Rather, the process of integration of politics and religion was one of negotiation with regional and local elites as well as the populace. Early modern states, with their limited bureaucracies and their resulting difficulties to govern and control their territories, had to rely heavily on the collaboration of regional and local elites, for example, noblemen and urban magistrates. If this collaboration was not forthcoming, religious and political attempts at unification often stalled or failed altogether. As a result, opposition and resistance to the introduction of the Reformation or measures of confessionalization were just as common in early modern Europe as compliance with such measures.

Third, especially with regard to the general population, it is important to differentiate between conversion – understood as the conscious adoption of a set of religious beliefs and practices – and conformity – defined as outward compliance with a church by law established in a certain territory. Although we cannot always tell whether a particular person had converted or 'merely' conformed, the significance of conformity as a group phenomenon cannot be overrated in early modern Europe. While both Protestant and Catholic reformers lamented the existence of various forms of popular religion, this usually did not affect the populace's general conformity with the established church. However, it did make a huge difference whether the majority of the population in a territory conformed with the state church

and participated in its rituals or whether they failed to do so and actively resisted the official church.

The Late Middle Ages

Historians today agree that the late Middle Ages laid important groundwork for the Protestant Reformation. In particular, attempts at reform of the Church through a general council were an important feature of the age as were a number of dissident or, as they were regarded at the time, 'heretical' movements. In addition, a number of different movements, both clerical and lay, attest to the broad reform efforts during the late medieval era.

The conciliar movement of the late Middle Ages aimed at a comprehensive reform of the Church through a general council. Although several great councils took place (above all, Constance, 1414–18, Basel–Ferrara–Florence 1431–49), and the conflict between the papacy and conciliarism was decided in favor of the papacy just before the advent of the Protestant Reformation, it remains an open question in historiography whether the reform of the Church had not sufficiently progressed by 1517 or whether, on the contrary, it had made so much progress that it was regarded as a threat in the more remote areas of the Latin Church such as Saxony.

During the late Middle Ages, there were a number of 'heretical' movements in different parts of Europe, which were of course religious movements in their own right, but were later regarded as precursors of the Protestant Reformation. The Waldensians sprang up in the region around Lyon in France in the twelfth century as a religious movement that shunned wealth and rejected the authority of the Church. After having been declared heretics, they were persecuted by the Inquisition throughout the late Middle Ages. The small surviving group took up the ideas of the Protestant Reformation in the sixteenth century.

In the fourteenth century, John Wyclif started the religious movement of the so-called Lollards, which focused on reading the Bible in the native language, and therefore rejected the veneration of saints and images. The Lollards were declared heretics by several church councils, but the movement survived in England until the sixteenth century when, just as the Waldensians, the remaining Lollards became part of the Protestant movement there.

Finally, Jan Hus, who was influenced by Wyclif's ideas, started the movement of the Hussites in Bohemia. He rejected papal authority, propagated reading the Bible in the native language as well as communion in both kinds (that is, for laypeople to receive the wine in addition to the bread). At the Council of Constance, Hus was convicted of heresy and burned at the stake. Nevertheless, the two branches of the Hussite movement, the Utraquists and the Bohemian Brothers, survived into the early modern period.

Various reform movements were active in the late Middle Ages, among others the Observant movement of the mendicant friars, the Humanist movement at the universities, and the Brethren of the Common Life, a lay movement which originated in the Netherlands in the fourteenth century. Overall, the late Middle Ages saw in intensification of lay piety in the form of the cult of the saints, pilgrimages and processions, and indulgences. While on the one hand, these movements confirm that the Protestant Reformation was part of a long era of change and reform that encompassed the late Middle Ages and the first half of the early modern period, on the other hand, the mixed image of the late medieval Church seemingly caught between crisis and revitalization continues to make it difficult for historians to explain how and why the Protestant Reformation took hold.

Protestant and Catholic Theology in the Era of the Reformation and Confessionalization

The theological ideas of Martin Luther and other reformers ultimately resulted in the division of Latin Christianity into multiple confessional churches. However, one should regard Luther himself as a man of the Middle Ages who wanted to reform, not divide, the Church. Luther's theology built upon medieval foundations, but it also, as Berndt Hamm has formulated, constituted a 'systemic break' in theological terms ('Systembruch') (Hamm, 1993: p. 79). Luther's theology was above all characterized by the so-called *sola* principles: *sola gratia*, *sola fide*, *sola scriptura* – by grace alone, by faith alone, by Scripture alone. Luther rejected the idea of salvation through works and postulated that man was saved only through God's grace. In addition, the Bible was to be the only authority in questions of faith, not the tradition of the Church. This resulted in a sweeping rejection of medieval beliefs and practices: Luther was opposed to indulgences and the veneration of relics and saints, he rejected the role of the priest as a mediator to God and postulated the priesthood of all believers. He also radically reduced the number of the sacraments from seven to two: baptism and communion, which the laity received in both kinds.

The Protestant movements, which emerged over the course of the sixteenth century, differed, above all, in their views of the Lord's Supper. While Luther rejected the idea of transubstantiation, he maintained the real presence of the body and blood of Christ in the bread and wine during communion. In contrast, Zwingli regarded communion as a memorial meal held in commemoration of the last supper of Christ with the elements serving only as symbols. Calvin developed a compromise version between Luther's and Zwingli's understandings of communion, arguing that Christ is spiritually (but not corporeally) present during the Lord's Supper.

In addition to the major confessional churches, radical Protestant groups emerged during the sixteenth century, especially the Anabaptists, a group that originated in Zwingli's Zurich. Anabaptists rejected the baptism of children and practiced adult baptism. Other radical positions, for example their strict interpretation of the priesthood of all believers and their refusal to take oaths, led to their being persecuted by the authorities, especially after the excesses of the Anabaptist Kingdom of Münster in 1534/35.

The Catholic Church responded to the theological challenge of the Protestant Reformation by clearly defining its own doctrines in the decrees of the Council of Trent. The council reaffirmed the doctrine of transubstantiation as well as the seven Sacraments. It stressed the dual nature of justification through both God's grace and good works, and emphasized the validity of tradition against the Protestant principle of *sola scriptura*. The major doctrines were enshrined in a new

confession of faith, the *Professio Fidei Tridentina*. In addition to these doctrinal decrees, the Council of Trent also promulgated a whole range of decrees concerning ecclesiastical reform. The gradual implementation of these decrees, together with the activities of new orders, not least the Jesuits (founded in 1534 by Ignatius of Loyola), resulted in the formation of a confessional church, which was active all over the world.

Germany during the Age of the Reformation and Confessionalization

Why did the Lutheran Reformation survive and even succeed? This question can only be answered by looking at the political, social, and communicative contexts and in particular the unique structures of the Holy Roman Empire of the German Nation. Very soon after Luther had sent his 95 theses against indulgences to the Archbishop of Mainz in order to start a theological disputation in 1517, the Reformation became a media event, thanks to the recently invented printing press with movable type. The 95 theses were translated into German and published, and Luther followed up with further publications. The heresy trial against him was opened in Rome in the summer of 1518.

Shortly afterward, the politics of the Empire first played out to the advantage of the Protestant Reformation. Because Pope Leo X wanted to recruit the Elector of Saxony, Luther's territorial lord, as a candidate for the Emperorship against Charles V of the Habsburg family, a heresy trial seemed inopportune and was suspended. While the Pope was not successful in preventing the election of Charles V, the pattern of provisional measures and repeated suspension of a more forceful policy against the Reformation and its supporters among the imperial princes and cities characterized the entire first half of the sixteenth century and ultimately secured the success of the Reformation.

Charles V was preoccupied with enemies and wars on two fronts: against Francis I of France and against the Ottoman Empire. As a result, he spent many years outside the Empire and was willing to compromise again and again on the question of religion, especially to receive the so-called *Türkenhilfe* (a levy because of the Turkish danger) from the imperial estates. For example, at the imperial diet of Speyer in 1526, it was decided that, in exchange for a *Türkenhilfe*, the imperial estates were allowed to regulate religion in their territories in whatever way they thought best. This and similar moratoria on the enforcement of the Edict of Worms of 1521 (which had declared Luther a heretic) opened the door for princes to establish Lutheran churches in their territories, a step which could not be undone later.

By 1530, the two parties had affirmed their doctrinal positions to such a degree that the first two confessions of faith were presented to the Emperor at the imperial diet of Augsburg: the Lutheran *Confessio Augustana* and the Catholic *Confutatio*. And in 1531, the first Protestant military alliance was founded, the Schmalkaldic League. After the Peace of Crépy with France in 1544, Charles V was finally able to turn his attention to the Empire. However, in spite of his initial success against the Protestants in the Schmalkaldic War of 1546/47 and during the imperial diet of Augsburg in 1548 when he imposed the Augsburg Interim, Lutheranism in the Empire could no longer be suppressed. An alliance of the German Protestant princes with the French king led to the Princes' War of 1552, which the Emperor lost. As a result, Charles V left it to his brother Ferdinand to negotiate a peace with the Protestant princes.

The Peace of Augsburg of 1555 legally established Lutheranism next to Roman Catholicism as a confession in the Empire. The territorial princes gained the right to determine the confession of their territory and their subjects (*ius reformandi*, later enshrined by imperial lawyers in the phrase *cuius regio, eius religio* – whose realm, his religion). In order to ensure that the imperial Church and the electoral college would remain Catholic, the so-called *reservatum ecclesiasticum* (ecclesiastical reservation) was inserted into the peace treaty. It stipulated that if the ruler of an ecclesiastical territory, such as a prince-bishop, converted to Lutheranism, the *ius refomandi* principle would not apply and the convert would lose his position.

In the early years, the Reformation had been a media event as well as a popular movement. Even though A.G. Dickens's dictum that the German Reformation was 'an urban event' (Dickens, 1976: p. 182) might be an overstatement, there can be no doubt that the success of Lutheranism in the towns and especially the imperial cities largely contributed to its overall success. However, in the long run, the cities were more vulnerable than the territorial states. In contrast to the territories, the cities did not gain the *ius reformandi* in the Peace of Augsburg.

The imperial knights and the peasants had proved to be even more vulnerable. The imperial knights, many of them early supporters of Luther, and the peasants who adopted Lutheranism in the early years of the Reformation are examples of the amalgamation of religious and political ideas and demands that would prove to be characteristic for the entire age. However, both groups lost the wars they waged against the rising territorial princes of the Empire (the War of the Imperial Knights in 1522/23 and the Peasants' War in 1524/25).

The Peace of Augsburg brought several decades of peace to the Empire while, at the same time, a civil war over religion was raging in France. As such, it can only be considered a remarkable success. However, the peace treaty eventually caused friction and conflict in the Empire because, in order to find common ground, the treaty contained many dissimulating formulations which, over time, proved to be open to contentious interpretations. Starting in the 1580s, an increasing confessional polarization took hold in the Empire. This was intensified by the implementation of Tridentine reform in the Catholic territories on the one hand and the conversion of a number of German Lutheran princes to Calvinism on the other. The Lutheran church, which had been deeply divided after Luther's death, also united and confessionalized with the Formula and Book of Concord of 1577/1580.

Between 1583 and 1618, several conflicts broke out in the Empire which highlighted the contentious aspects of the Peace of Augsburg (for example, the Cologne War of 1583, the Donauwörth conflict of 1606, the succession conflict in Jülich-Cleve-Berg in 1609). As a result, the imperial institutions were paralyzed and military alliances were founded in 1608 (Protestant Union) and 1609 (Catholic League), respectively. Confessional war was increasingly on the horizon and because of the deep European connections of the Empire and its ruling families, this could only be a European war. It eventually broke out in 1618 in Bohemia, where the Protestant Bohemian

estates had rebelled against their Catholic Habsburg king and elected the Calvinist Elector of the Palatinate, Frederick V, instead. Thus, the Thirty Years' War began.

Europe during the Age of the Reformation and Confessionalization

We have seen above that both the processes of Reformation and confessionalization could result, on the one hand, in the religious and political integration of a city or territory under one confession or, on the other hand, in religious and political resistance and war. In conclusion, a brief 'tour' of early modern Europe serves to illustrate this further.

The religious integration of the recently united kingdoms of Spain was successful because early Protestant stirrings were quickly suppressed with the help of the Inquisition and a strong identity, which combined religious and proto-national elements, was established. Similarly, the Scandinavian kingdoms, Denmark and Sweden, successfully integrated Lutheran church building with state formation. The kingdom of England also belongs to this group. Queen Elizabeth I managed to establish Protestantism as part of national identity by favoring a gradual process of Protestantization in her realm.

However, England was, in fact, a 'composite monarchy' (Elliott, 1992) in the early modern period, which consisted, after 1603, of England, Wales, Ireland, and Scotland. While Wales was successfully protestantized, Ireland was not. Here, a defense of 'old traditions' in the political realm combined with a Catholic identity newly invigorated by Tridentine missionaries to serve as rallying points for resistance against encroachment by the Protestant English state and church. Scotland rebelled against England in the middle of the seventeenth century when it feared that its Calvinist consensus was under threat by the English crown and its state church.

In France, the spread of Calvinist ideas in the sixteenth century led to the establishment of a powerful Protestant (Huguenot) movement, both in political and social terms. The resulting confessional split in French society led to a civil war between 1562 and 1589. With the Edict of Nantes of 1598, King Henri IV (who had converted to Catholicism and to whom the sentence 'Paris is well worth a Mass' has been ascribed) enforced a legal settlement which ensured Catholic-Huguenot coexistence in France. However, King Louis XIV's revocation of the Edict of Nantes in 1685 attests to the fact that the ideal of a kingdom unified in religion (*un roi, une foi, une loi* – one king, one faith, one law) was still very much alive in the late seventeenth century.

And finally, two territories of the Habsburg dynasty, the Netherlands and Bohemia, are striking examples of how the connection between state formation and confessionalization could provoke massive resistance and lead to war. In both dependent territories, oppositional movements of the estates, which originally resisted centralization and state formation, became intertwined with confessional resistance against (re-) catholicization. In the case of the Netherlands, this resulted in the Dutch Revolt and an eighty years' war with Spain. In the end, the Dutch Republic became an independent state with the Calvinist church as its 'public' (i.e., official) church. In the case of Bohemia, the defeat of the Calvinist Elector of the Palatinate and short-term King of Bohemia Frederick V in the Battle of the White Mountain in 1620 resulted in the replacement of the majority of the Bohemian elite and a thorough process of recatholization of the territory.

Only in Switzerland and in the German Empire did the dualistic political structure, which prevailed in both countries, lead to the long-term establishment of multiconfessional political entities. While the existence of more than one confession was legally established in the larger political entities, most of the smaller political units (territories in the Empire, cantons in Switzerland) were mono-confessional. While the Reformation and the confessional age had lead to the division of Latin Christianity into multiple confessions, the ideal of the unity of church and state continued to prevail in Europe until at least the end of the seventeenth century.

Refugees in Anthropology

Marita Eastmond, University of Gothenburg, Göteborg, Sweden

© 2015 Elsevier Ltd. All rights reserved.

Abstract

The article outlines the development of 'refugees' as a legal category as well as an academic field of study, in response to global refugee crises in the twentieth century. It also presents some key concepts and themes of research, and demonstrates the particular relevance of anthropology for the study of refugees, including some of the challenges of global movement to the discipline and its ethnographic method.

Refugees as a Field of Study

People forced to leave their homes to settle in new environments is not a new phenomenon. However, 'refugees' as a legal category and as the object of academic research are more recent. This article will outline the development of refugee studies in response to global refugee crises in the twentieth century. It will also present some key concepts and themes of research and demonstrate the particular relevance of anthropology to this field.

The study of refugees emerged in the 1980s as an academic field in its own right, with its own research centers, associations, academic degrees and international journals. Until then, international migration had been the main academic context for research on refugees and displaced people. The establishment of refugee studies was related to the global refugee crisis at the time. By 1981, the escalation of violent conflicts and mass disruptions in many parts of the globe had dramatically doubled the global refugee population in three years. New increases followed the political changes at the end of the Cold War, with large numbers of refugees from upheavals in postcolonial states and from crumbling Communist federations in Europe dominating asylum claims in the 1990s. In 2001, the pivotal events of September 11 and the subsequent wars on terror produced mass refugee movements, notably from Iraq and Afghanistan, while concerns with 'securitizing' borders, especially in northern states, have tended to criminalize and sanction asylum seekers. The numbers of refugees and asylum seekers remain high at the end of 2010, but given the increasingly restrictive migration regime in the north, people in need of safety are increasingly seen to be making their way to other destinations, notably emergent middle-income countries in Africa, Asia, and Latin America (UNHCR, 2011; Van Hear, 2011).

Since its inception, refugee studies have been multidisciplinary, drawing together a range of research from the social and behavioral sciences, such as political science and peace and conflict studies, medicine and psychiatry, and always with a strong presence of international law and anthropology. Refugees have also become an established research topic in recent years in anthropology's own subdisciplines, notably development anthropology, medical anthropology, legal anthropology, and the anthropology of policy. With its clear relevance for the acute issues of many refugee situations, anthropology has engaged with practical application and advocacy, often in cross-disciplinary teams. Its specific contribution in these contexts has been to elicit and promote refugees' own voices, through ethnographically informed analyses of refugees' predicaments and perspectives, in relation to the group's specific history and context of displacement. In the past two decades, however, policy and practice of states and their bureaucracies in dealing with refugees have themselves come under anthropological scrutiny. Moreover, researching dispersed and vulnerable populations across different sites have meant great challenges to studies relying on ethnographic methods. The multidisciplinary character of this field, as well as the increasingly complex geopolitical dynamics and changing migration regimes, spawns ongoing debates about refugees as an object of study.

Who Is a Refugee? Legal Definitions and Academic Concepts

The historical contexts in which refugees emerged as an internationally recognized category were the massive displacements in Europe following two world wars. The Geneva Convention of 1951 is the critical landmark of the establishment of institutions (such as the UNHCR) and legal instruments to protect and assist such populations still valid today. A *convention refugee* is an individual who has crossed a national boundary, and has a well-founded fear of persecution in the country of origin on the basis of race, religious or political affiliation, ethnic or social group. Subsequently, other, regionally based legal conventions, notably in Africa and Latin America, have adopted more inclusive definitions of refugees which better correspond to the manifold types of mass displacements that often follow violent conflicts and other social disruptions in their regions. Also many other states today recognize *people in refugee-like circumstances*, i.e., persons who are outside their country of origin and face protection risks similar to those of convention refugees; although not personally persecuted, they are victims of war or other social disruptions. Categories outside of legal provisions but equally of concern to agencies of protection, as well as to research, are *internally displaced people* (IDPs), those who do not cross an international border but flee within their own countries. Of concern are also the many refugees and IDPs who voluntarily return to their places of origin.

These legal categories notwithstanding, the answer to the question 'Who is a refugee?' remains a crucial one in today's world. Legal categories are subject to the interpretations made

by receiving states and their policies of admission may differ in response to foreign policy interests, public opinion and perceived 'load' of new arrivals. For those being classified, it may be a matter of life or death, because of the exclusive rights and entitlements of humanitarian concern and international protection that come with refugee status.

In the academic field, the question is also a continuing concern as a matter of theoretical and conceptual delineation of its object of study. 'Refugees' as defined in the Geneva convention and based on individual persecution is too narrow, many argue, both as a protection instrument and as a theoretical concept and does not take account of the complexity of many situations which force people to leave their homes and in which violent conflict and insupportable living conditions, the political and the economic, are often interlinked. Thus, according to Van Hear (2011), 'forced migration' would be more useful as an analytical concept in social science rather than 'refugee studies,' as it takes account of the complexity of motives of moving and also recognizes the need to think of refugees as social actors exercising agency and making choices, however, pressing the circumstances. Both terms may be distinguished from what is meant by 'refugee' in public discourse, or emically, as defined by refugees themselves. Others underline the importance of maintaining that which is specific to refugees, in terms of human rights and other humanitarian provisions made in their name (Shami, 1994) and legal researchers are wary that a shift from the study of refugees to the more inclusive one of 'forced migration' will dilute their protection and thus respond to the interests of northern states (Hathaway, 2007, Chimni, 2009 in Van Hear, 2011).

The burning issue of who and what a refugee is can also be addressed by examining the powerful institutional contexts and discourses, national and international, in which the category of 'refugee' is construed and public policy shaped. Important inspiration from anthropology has been drawn from theories concerned with the politics of space and otherness (Gupta and Ferguson, 1992, 1997) and in particular from Liisa Malkki's work which opened up for conceptualizing the anthropological study of displacement in new ways. According to Malkki, the category of 'refugee,' emerging from policy frameworks grounded in a particular history and view of the nation-state order, had been uncritically adopted into research as well as practice. The 'refugee experience,' following this logic, was defined by loss and uprooting, and depicted as an undifferentiated and essentialized condition for which repatriation was the best solution (1995a). In a world where the nation state is seen as the 'natural' basis of belonging, Malkki argued, refugees become an anomaly that challenges the dominant 'national order of things' (Malkki, 1995b). Eschewing such essentializing notions, anthropological research today is more likely to examine not only the political and historical circumstances that force particular people to move but also the meanings they themselves attribute to their displacement.

The Dynamics of Displacement

Forced migration then is inevitably related to change, often acute and disruptive, and any theoretical approach to refugees necessarily engages with process. In some cases, displacement affects most aspects of life and addresses core issues in the anthropological study of communities, such as subsistence and livelihood, kinship and family, social and political networks as well as the cultural meanings which give a sense of coherence and predictability to everyday life. For those displaced, change is often multifaceted and compressed in time, thus also providing a challenge to an older generation of anthropologists more accustomed in the past to studying slower and more cumulative processes of change.

With a shift in recent years to an emphasis on the workings of power in contexts of reception, as well as the agency of refugees themselves, anthropologists have taken a greater interest in uncovering the perspectives and strategies through which displaced groups deal with disruptive change, renegotiate livelihoods, social relations, and identities. A growing body of research in the anthropology of war and violent conflict, population movement, and reconstruction is contributing important theoretical approaches to understanding the interplay between concerns and strategies of people on the move with processes at global and state levels (Jansen and Löfving, 2008).

A Diversity of Refugee Situations and Research Themes

However, these processes unfold differently in different places. The great diversity of conditions, in particular the contrast between southern and northern host states, has meant the development of different emphases in the concerns and theoretical approaches applied to the problem of refugees in different parts of the world. Differences reflect the global distribution and politics in terms of admitting refugees: Today, as before, three-fourths of the world's refugees reside in a country neighboring their own. Only a trickle make it to the more affluent receiving countries of the north, in Europe or in North America, and even fewer are allowed to settle there.

Thus, in *southern* countries, particularly in Africa and Asia, displacement and refugees have often been studied as a problem of assistance and development (Bakewell, 2012). A particular theme concerns the consequences of development schemes and modernization, forcibly displacing large numbers of people within their countries. An early contribution is Elizabeth Colson's classical ethnography of the social and cultural consequences of the relocation of the Gwembe Tonga due to the building of the Kariba hydroelectric dam in the Zambezi River Basin in 1958 (Colson, 1971). Another major research theme in southern contexts has been a concern with *humanitarian assistance* to refugees, and the potential of such programs to have more long-term development effects that also benefit the country and the local communities that host them. One of the first studies of this dynamic interaction between different actors and agencies was Harrell-Bond's illuminating ethnographic study (1986) analyzing the implications of relief operations on refugees and their hosts in Uganda. Neglecting refugees' own concerns and resources, the interventions of relief agencies were found to create conflicts and fragmentation both within refugee collectivities and with the local resident population. If and how displaced people define themselves is also a question of how they perceive their prospects. Malkki's

ethnography (1995b) of displaced Hutu refugees from Burundi settled in Tanzania compares identity and historical memory of refugees in camps to those who have settled in a nearby town, relying on their own creative strategies for survival. Whereas these were pragmatically juggling social identities, in the diversity typical of many African towns, camp refugees were passionately concerned with creating their mythico-history as members of the Hutu nation. The strength of ethnographic fieldwork is that it allows 'a critical examination of camps as organized solutions to refugee crises,' while also dispelling the one-sided image of refugees as dependent and passive victims. An example of this more complex picture is Cindy Horst's analysis of how Somalis cope with refugee life in Kenyan camps. Emphasizing agency rather than victimhood, she describes the variety of social and cultural resources in dealing with camp life; these include a high degree of mobility and strong social networks that stretch far beyond the confines of the camp (2006).

Most of the world's refugees are in protracted situations, reflecting prolonged conditions of violence and instability in their countries of origin. For the many who move back and forth across borders or inside their country in response to new outbreaks, distinctions between flight and homecoming, or refugees and internally displaced lose their meaning (Allen, 1996). Others get stuck in what is often referred to as refugee warehousing, involving the confinement in camps or segregated settlements in remote or near-border areas (USCRI, 2009). Such confinement may last for years (e.g., Afghans in Iran and Pakistan) or even generations (Palestinians in Lebanon, Gaza, the West Bank).

'Going home' has been promoted in international policy as the most durable solution to refugee problems and the naturally desired end of 'the refugee cycle' (Black and Koser, 1999). The return of refugees and IDPs has also become a strong priority of international peace building efforts in war-torn societies in recent decades. The international repatriation discourse has often portrayed return within an essentialized conception of identities as rooted – as people coming back to their 'natural' homes, often predicated on an idealized notion of prewar local life. But rather than assuming rootedness, anthropologists have emphasized the need to see attachment to place as contingent on wider social and historical processes through which people lay claim to a place and call it home (Gupta and Fergusson, 1997). This has constituted an important theoretical framework for the study of the repatriation of refugees, as seen for instance in ethnographies of return (Stefansson, 2006) as well as in studies of the creative ways in which new places are made into home by returnees (Hammond, 2004). Studies in different parts of the world attest to the fact that images of home in exile cannot always be reconciled with the realities of life upon return, and that reemplacement requires negotiating one's entry in a new context of power and difference (Allen and Morsink, 1994; Black et al., 2006; Kamal, 2010; McDowell and Eastmond, 2002). In such conditions, repatriation is almost always a 'struggle for home' (Jansen and Löfving, 2008).

In *northern* contexts, the resettlement and integration of refugees have been predominant research themes, at least until the 1990s. Current frameworks have moved away from more of these conventional community studies that focused on a particular group and its sociocultural integration, often based on the idea of 'culture' as shared tradition (O'Neal, 1999). Subsequently, more processual perspectives have underlined the ways in which 'culture' and 'ethnic identity' are negotiated or reinvented, and the meanings that groups attribute to their exile (DeVoe, 1992). In the conventional migration paradigm, continuing attachments to the country of origin were often interpreted as poor social integration, a notion subsequently dispelled by the transnational frameworks of migration emerging in the early 1990s.

Current research, in anthropology as in other social sciences, reflects a growing concern with the increasingly restrictive refugee regime in northern states, particularly in the EU. The measures undertaken to manage migration include policies to control and deter 'flows' from the outside, for instance by exporting asylum processing or confinement of applicants to the margins of EU, such as Malta (DeBono, 2011) or, by agreement, to transit or source countries outside of EU (Betts and Milner, 2006). Anthropologists' new interest in borders and legality includes exploring states' regulation of movement (Khosravi, 2011). Given that it is nearly impossible for claimants to meet the demands for legal entry, the restrictions give rise to new categories, such as irregular, undocumented, or illegal migrants, thus tending to criminalize asylum seekers and legitimate their forced removal. With respect to the conceptualizations made in the policy field, Turton (2003) reminds us that categories and images are powerful means of constituting, not merely reflecting, reality. The terms by which we describe forced migrants are not innocent but are part of how we interpret and therefore act toward those who are displaced. Zetter's (2007) article on refugee labeling in the context of public policy practices illustrates this process of the making of bureaucratic categories, and the consequences for those categorized, and offers insights into the impacts of institutional and bureaucratic power on the lives of refugees. For this reason, anthropologists' study of public policy, its role, and consequences in contemporary society, including the managing of migration, is a promising line of inquiry (Shore et al., 2011). Public policy research entails scrutinizing the assumptions of public policy 'as a legal-rational way of getting things done' and illuminating the constellation of actors, activities, and influence that shape policy, how they are implemented, and what their consequences are for those concerned (Wedel et al., 2005: 30). In a similar vein, recent ethnographic studies address the procedures of managing unwanted migrants, the discourses that underpin these procedures, and the responses of those they address. Khosravi (2009) has examined a detention center in Sweden and how officials formulate their task in terms of motivating and assisting detainees in returning. Griffiths (2012), doing fieldwork in a detention center in the UK, analyses how failed asylum seekers awaiting deportation negotiate discourses of identification and criminalization. Whyte's (2011) ethnography of life at a Danish reception center describes the techniques of surveillance of asylum-seeker residents as a kind of myopticon, and the strategies of evasion and resistance of the residents. Along similar lines, new interest comes from legal anthropology, directing attention to the legal and bureaucratic systems and discourses through which asylum claims are processed (Good, 2007). The system also enlists anthropologists, in some EU countries at least, in a new role as expert witnesses in asylum courts (Good and Gibb, in press).

Refugee Children

An increasing number of claimants in recent years have been unaccompanied children, three-fourths of whom make their way to Europe, often after a long and hazardous passage from countries of origin in Asia or Africa (Watters, 2008; Kohli, 2006). Reflecting the culture of mistrust of contemporary European reception systems, two conflicting images of these children, similar to those used to depict adult asylum seekers, have emerged: the vulnerable victim or the bogus untruthful opportunist (Giner, 2007; Griffiths, 2012). Age determination procedures, notoriously unreliable, to decide whether applicants qualify as children reflect a reluctant and mistrusting system. The public controversy in Sweden over asylum-seeking children in the early 2000s, which engaged the public and nearly toppled the government, is a case in point. Asylum-seeking children who feared deportation developed a condition of severe apathy which took epidemic proportions but for which there was no clear-cut medical diagnosis. In the public debate and the contrasting images it spawned, children were either seen as victims of the state rejecting them or, as state experts maintained, malingerers seeking permanent residence in Sweden. Eventually, the government introduced a temporary law through which most of the children and their families were eventually granted residence status (Eastmond and Ascher, 2011; Hacking, 2010). The well-being of refugee children has drawn attention from a range of disciplines, not least psychology and pediatrics. Ethnographies of children and youth in camps in southern countries (Atkinson, 2006; Chatty, 2010) or received in the north (Watters, 2008) examine children's experiences and needs, as well as the interventions made on children's behalf in terms of health and social care. Theoretical concerns are notions of childhood and children's agency; other concerns are the different, more experiential, methods required when working with children.

Health problems of refugee children as well as adults have been addressed by medical anthropologists (Watters and Ingelby, 2004). Anthropologists caution against identifying disorders such as traumatization and posttraumatic stress disorder (PTSD) across cultures and call for ethnographically grounded emic understandings of such responses. While diagnostic labels may be convenient categories for clinicians, they may pathologize refugees and their responses to violence (Eastmond, 2005; Parker, 1996). The issue forms part of a broader inquiry into the political and moral issues of reformulating injustice and violence as suffering and trauma (Fassin and Rechtman, 2009).

Refugee Diasporas

Reflecting increasing globalization, and thus eclipsing the north–south distinction, much research is today directed at diasporas, the global networks of refugees and migrants and their transnational practices. Diaspora was introduced as a useful concept in anthropology in the 1990s (Safran, 1991; Clifford, 1994); it referred to populations dispersed by force, maintaining over long-time relations to, or at least a dream of, homeland and return. Today, the term encompasses different categories of migrants (including 'ethnic communities') who retain ties to people in other parts of the world and engage in diasporic practices (Brubaker, 2005). Diasporas and their economic resources today have recognized importance for the global economy, and 'diaspora' has been adopted as a policy term used by governments and development agencies (as well as in migrants' own discourse) to harness the potential that such networks represent (Van Hear, 2011). At the level of the household, remittances have long played a vital role in patterns of support to people 'back home,' including enabling other family members to migrate. Transnational migration and diaspora have thus reshaped the traditional paradigm of migration as a one-way, permanent move. While 'permanent integration in another country' has long been defined by the UNHCR as the second best solution for refugees when return is not possible, such distinctions are no longer that clear. For refugees themselves, transnational lives can resolve the conflict between 'here' and 'there' or between the ideological commitment to return and the practical realities of everyday life (Eastmond, 2006; Fuglerud, 1999).

Refugees: Ethnographic Challenges

Ethnographically, anthropologists would ideally follow the refugees, the routes they take and the connections they make. Such observational strategies are rarely feasibly except in auto-ethnographies (Khosravi, 2011). In most cases, the focus is on one or two of the local contexts in which refugees' lives are embedded, usually the country of asylum and that of origin, and possibly a relevant selection of sites in their global network. Given this dispersal of places and relations in a global field, the greatest challenge is one of access and depth. Still, multisited ethnography is not that novel and much can be learnt from drawing upon research into many other globalized phenomena besides migration (Hannerz, 2003). Some refugee sites are more inaccessible than others, however; camps or detention centers may curtail observation and limit researchers' access to informants. Others may be bureaucratic worlds and legal procedures that may seem as foreign and confusing to the refugee as to the ethnographer (Hannerz, 2003). Such fields may thus entail entering unfamiliar territory 'at home' and require interaction with immigration officers, deportation escorts, and other officials of the state, or appearing as expert witness in asylum courts (Good, 2007). Access and understanding can be difficult also in other ways. To elicit narratives of torture, flight or detention, or other experiences of loss and personal pain require sensitive approaches and strong ethical awareness, especially when working with unaccompanied children (Kohli, 2006).

The Future of Refugee Studies

From having been rather marginal as a research area until the 1980s (in interesting ways reflecting the position of displaced populations themselves), the anthropology of refugees and forced migration is today an established field of research. Linked to and accentuating globalization and global geopolitics, refugees have presented a challenge not only to nation states, but also to the social sciences. Increased mobility and

transnational forms of social organization have required anthropology in particular to reexamine its concepts of culture and community as bounded and territorialized units. Refugee studies have been instrumental in this conceptual move away from the 'people and places' to a greater focus on the processes of making and maintaining connections between them.

While the study of refugees shares some common ground with international migration, it will have to continue addressing the circumstances of force that produce refugees as well as the politics of reception in the context of tightening refugee regimes. With theoretical development in recent decades in the anthropology of conflict, violence, and social memory, globalization and diasporas, security and human rights, the study of refugees and exile as transnational phenomena has gained new relevance and provided fresh theoretical insights. These issues will increasingly engage and infuse new ideas in the domains of moral and political anthropology, including a waxing interest in legal anthropology and in studying public policy 'at home.' The broadening of areas of anthropological inquiry and the increasing relevance of core anthropological concerns signal the coming of age of the study of refugees as an academic field. If refugees are symptomatic of the state of the world, with global mobility, fluidity, and fragmentation, and increasingly global networks and multiple allegiances as well as claims to particular lands and cultural identities, then refugees will continue to be a central area of study in anthropology.

Refugees: Geographical Aspects

Abstract

'Refugee' is not a neutral descriptive term denoting people who have fled; it is a legal and political term and the way it is bestowed speaks to placemaking activities of the state. The contribution that geographical approaches to refugees makes is in studying the relationship between 'refugeeness' as a general condition of forced displacement and the legal category refugee bestowed by states. States are manifestations of a territorial take on political life; geographers do well to illumine the connections between territoriality, place making, and refugees.

The term 'refugee' is used by states, international organizations, and aid agencies to recognize and to govern individuals who have fled their countries of origin for specific reasons. In practice, states have exercised considerable leeway in determining who counts as a refugee. The 1951 Geneva Convention on the Status of Refugees defines a refugee as one who has fled his or her home state to another state because of persecution that the state either sponsors or is unable or unwilling to prevent. States are therefore the central parties in determining refugee status. This is despite the existence of the United Nations High Commissioner for Refugees (UNHCR), which acts as an expert and advocacy body conveying best practice for assessing refugee claims, but in most cases has little authority. The authority with the most capacity to determine who may be legally recognized as a refugee and who not is one that is centered on states. In other words, 'refugee' is not a neutral descriptive category; it is a prescriptive term of government. A geographical account of refugees begins at this juncture – between an ostensibly neutral description of individuals who are displaced and a prescriptive account of who counts as a refugee. The former gives an account of numbers and movement across space and territory; the latter focuses on the spatial and territorial practices – practices of making place – that people claiming to be refugees must negotiate, avoid, submit to, or resist. Practically, this involves studying the cultural, economic, and political practices that give territories their specific flavor across different scales and how these influence how states respond to – or fail to respond to – refugee claims.

A geographical treatment of refugees must include, but cannot be limited to, a survey of where refugees are distributed across the world. Central to any understanding of geographical aspects of refugees is an account of how they are governed and the spatial issues involved. As refugees move from a place of persecution to a place of possible protection, they are caught up with different economic, political, and cultural practices that constitute the meaning of the spaces they move in or toward.

Studying this geographical juncture involves looking at the different points at which individual or group displacement meets placemaking activities. One way of doing so is to study the movement of refugees. In a somewhat stylized – but still useful – account, this movement has three stages: flight from places of residence across an international border; capture, reception, and assessment at another international border; and either refugee status bestowed or refused in a host country; the main issues here are deportation and conditions pertaining to the right to remain. This qualitative account seeks to add color and social nuance to a more neutral account of refugees – embodied, for example, in the 1951 Convention and in the UNHCR Charter which I describe later – that say refugees are individuals forced by persecution or social collapse to move outside their country to another country to seek protection. This definition does not focus on the spatial practices of making place that can influence how refugees move and how their reasons for moving are perceived. Unlike the neutral account of refugee movement in the 1951 Convention and the UNHCR Charter, examining actual practice may allow us to read the social geographies that refugees encounter and must deal with.

The International Refugee Regime

The central document influencing refugee recognition and the way states and the UNHCR relate to refugees is the 1951 Geneva Convention on the Protection of the Rights of Refugees. That document outlines obligations states have toward refugees and lists factors to take into account when determining refugee status. The key factors are that refugees must have experienced or be in threat of persecution that the state either sponsors or is unable or unwilling to contain and that refugees must be outside of the country of their origin. Central to the 1951 Convention, and to all subsequent analyses and recognition of refugees, is this state-centered and international aspect. Refugees must move beyond borders to another state because their home state is unable or unwilling to protect them.

Article 1 of the 1951 Geneva Convention Relating to the Status of Refugees applied the term to.

> [Any person who] … owing to a well-founded fear of persecution for reasons of race, religion, nationality, membership of a particular social group, or political opinion is forced to migrate involuntarily across an international boundary and remain outside his country of nationality.

Cause, motive, and political boundary thus became the classic benchmark determiners of refugee status. The 1951 Refugee Convention specifically addressed the status of Europeans displaced by World War II. An amended 1967 Protocol established legal standards for refugees everywhere. Although the 133 signatories are not required to provide asylum to refugees, they are prohibited against refoulement – expelling or returning refugees to countries where their life or freedom would be threatened (Hamilton, 1999).

In 1951, the United Nations (UN) General Assembly created the Office of the UNHCR with a brief 3-year life span in mind. In 1954, however, the Assembly extended UNHCR's mandate for another 5 years. Successive 5-year renewals have followed ever since. UNHCR is charged with refugee protection and the promotion of lasting solutions to their displacement The organization advocates the protection of refugees in would-be host countries and assists and protects returnees who repatriate to their home countries and groups of people who face refugeelike situations within their country of origin. Such assistance may include developing refugee integration programs, managing refugee camps, disseminating country information to states to assist them in making decisions and relief work in refugee situations. The UNHCR is also active in states that are not signatories of the Geneva Convention where they assess asylum claims and provide letters of protection, which states recognize at their prerogative.

The condition of forced migration applies to more than 34 million of the estimated 100 million permanent migrants worldwide. Of these, around 20 million are internally displaced persons (IDPs). IDPs are forced to move due to explicit forms of persecution or armed conflict or because of natural or man-made disasters and are not normally seen as legitimate refugees because of the Convention's bias toward movement across state borders.

Flight

Although geographers, starting with Ravenstein's work in the late 1800s, have long studied voluntary migration, their analysis of forced migration lagged behind. At the 1950 meetings of the Association of American Geographers, Proudfoot introduced a ninefold categorization of refugee population. That paper constitutes an early example of geographic work on the specific topic of refugees. Geographers thus began documenting the flight and distribution of specific refugee populations and have continued to do so.

Refugee research, including that of geographers, has grown substantially during the last 25 years (Hyndman, 1999). Refugee study programs now exist at universities in Canada, Egypt, Great Britain, Kenya, Sweden, and the United States. Academic interest has correlated with the growing magnitude of refugee crises worldwide; numbers of refugees, including IDPs, increased from less than 3.5 million in 1977 to more than 20 million in 2012 but the magnitude of refugees is also cultural, political, and economic and this is often evident in discourses and practices that see refugees as a threat to a national fabric (Bigo, 2002).

During the 1980s, refugee research largely focused on the first and third stages of the refugee experience, the processes of flight and resettlement. Resettled Central Americans and Indo-Chinese in the United States were the focus of study in more developed countries. That East Africa had become the epicenter of refugee crisis in the developing world was reflected in books on Eritrean and Ugandan resettlement (see Rogge, 1985; Harrell-Bond, 1986; Bulcha, 1988). A basic distinction was frequently made between assisted refugees housed in UN-sanctioned camps or settlements and unassisted refugees who either self-settled in rural areas or in urban centers (Wijbrandi, 1990).

Over the past 20 years, considerable attention has been paid to understanding 'flight' as a specific component of the complex movements that refugees undertake. Entwined with attention to movement and mobility are accounts of immobilization. Diken (2004) and Agier (2002) argue that refugees and displaced peoples are subject to concerted efforts by states, security personnel, the UNHCR, and sometimes asylum bureaucracies to contain, direct, or control their flight. As a result, people in flight are directed to camps or various types of holding centers. What occurs then are attempts to quarantine refugees away from the normal social, economic, and political environment. Refugees and displaced people on the move, in flight, are cast as people to be concerned about, the territorialization of identity headed by the state calls for political and social being that is settled and domesticated (Dillon, 1999).

White (2002) argued that the rise of refugee studies as a discipline contributes to a static depiction of refugees characterized by simplified models of community, home, and place. These are models that owe much to the dynamics of aid funding as well as to security discourses. From around the mid-1990s as a response to increased displacement of groups and individuals due to civil strife or environmental disaster, the concept 'complex humanitarian emergency' was articulated and employed to manage and help internally displaced people (Hyndman, 1999). Under conditions of complex humanitarian emergency, many actors are involved in managing displaced people (the state does not necessarily dominate). The UNHCR and international aid agencies frame displaced people as individuals or groups in need of help or assistance.

The consequence, argues White (1999), is that the focus becomes how flight may be straightforwardly managed from a humanitarian emergency perspective. A key assumption is that space is a neutral element and that refugees may be understood holistically and isolated from the spaces in which they move and live. One consequence is that refugees are viewed as a specific population, different from other populations in a given territory. They become a category of humanitarian government with the chaotic reality of living and moving through social space becoming subsumed to a systematic and coherent conceptualization of displaced persons as victims requiring humanitarian aid (and not as political subjects) (Malkki, 1996). The multiple ways in which individuals connect to place and community become secondary, and the differences within refugee populations that mean there are multiple identities and connections stretching across scales become less important. Refugees are understood as self-contained communities and as needy individuals. One result is that differences among refugees – how they move or the extent of their capacity to influence their social

environment – become neglected relative to the emphasis placed on their systematic management.

To recap then, geographers and sociologists have noted that at the moment of flight, people become trapped by a discourse and practice of "complex humanitarian emergency," which simplifies how displaced people relate to space, and the reasons for their displacement. Further, this discourse and practice ends up depoliticizing refugees: the primary way they are seen is as victims of humanitarian emergency; they are not seen as people who may have different degrees and experiences of displacement and of the causes of displacement. Displacement is a political condition: those who flee and are less able to cope with the conditions of displacement are those already marginalized by society, for example, the very poor or in some cases, women.

The UNHCR estimates that in 2012 there were 28.8 million internally displaced people in the world. The UNHCR also estimates that, at the beginning of 2012, there were 10.8 million refugees in the world. Numbers of refugees fell slightly in 2012 but numbers of internally displaced people have steadily increased. In 1997, there were around 17 million internally displaced people. In 2012, around 6.5 million individuals were newly displaced, a significant rise on the 3.5 million of the year before. The majority of displaced people are in sub-Saharan Africa, with the largest number of newly displaced people located in the Middle East and North Africa, a result of recent conflicts in that area. More people are becoming internally displaced, but fewer are crossing international borders. One reason for this may be their treatment as humanitarian victims immobilized in camps, another may be the successes that would-be receiving countries have had in preventing displaced people from crossing borders. This point will be examined in the next section, on borders.

Encountering Borders

In 1990, the locus of the global refugee population was the Global South. Developing countries hosted nearly 97% of all refugees. Conflicts in Afghanistan, Ethiopia, and Mozambique produced populations that each numbered in the millions. The Palestinian community (estimated at up to 4 million) had long since become permanent stateless exiles dispersed throughout the Middle East. Together, these four groups accounted for more than 13 million of the 16.6 million refugees worldwide. Yet, refugees could be found among more than one hundred different countries. And exile periods were lengthening.

During the 1990s, geographers diversified their approach to match the growing complexities of the refugee picture (Black, 1991; Black and Robinson, 1993). Moving beyond a 'refugee-centric' perspective (Chambers, 1986), scholars treated refugee settlement less often as if it were a self-contained process in isolation. Bascom (1993), for example, related the larger processes of rural transformation and agrarian change to that of refugee settlement. Although media images give the impression that refugees are mass 'flows,' it became abundantly clear that ethnic, age, gender, and class differentiation exist among uprooted populations (Bascom, 1998).

More recent scholarship by geographers has focused on the specific imaginings of the border that are discursively repeated and embedded in the state and nonstate institutions that refugees negotiate with. The centrality of the national border to refugee assessment rests on the way it is deployed as a way of imagining and realizing a national unity. Grundy-Warr and Wong (2002) argue that this imagination in Burma led to the displacement of hundreds of thousands of villagers from border areas populated largely by national minorities. In the quest for national unity, the state perceived minorities near the border as threatening. The taint of the border carries, meaning that individuals and groups denoted as not having a right of belonging in a territorially delimited 'national unity' tend to be approached at best with caution and at worst with prejudice by receiving states. Refugees are perceived as entering a preformed space, where they are to "conform to existing patterns of socio-spatial identity" (Newman and Passi, 1998: 190) with consequences for settlement or integration programs, as I will explore in the next section, as well as for asylum assessment policies at the border.

Receiving countries increasingly describe refugees as threats (Mountz, 2010). Boat people are criminalized; camps and holding centers are set up offshore. Over the past decade, Australia has developed offshore processing centers in nearby countries Nauru and Papua New Guinea (Prem Kumar, 2004). Geographers have used these and other examples to argue that borders are not static entities but instruments of control deployed against perceived threats as a way of making good sovereignty (Hyndman and Mountz, 2008).

In studying refugees' varied encounters with potential receiving states, scholars illumine not only the condition of 'refugeeness' (Malkki, 1995), but also how territorialization as the basis of modern politics occurs. Studying refugees is then an opening into studying how politics is constituted. Scholars have argued that territorialization contains human rights within national borders. Some scholars have deduced that refugees are without rights as a consequence, though it is perhaps more correct to say that refugees may be treated by individual states as though they have a lesser complement of rights. As it proclaims a national unity, the border develops a cultural power that state institutions and media deploy to show national belonging and nonbelonging. Refugees then become individuals who at least potentially are figures upon which the state can perform its power.

Some states create formal or informal 'buffer zones' that restrict refugees from entering into its territory. Australia, for example, has exploited its unequal relationship with small Pacific countries to create offshore processing procedures in exchange for aid in Nauru and Papua New Guinea. By creating a buffer zone, Australia effectively divests itself of its responsibility under the Geneva Convention to assess refugee claimants. In the European Union, in order to curb the movement of refugees across the Mediterranean, Italy and Libya cooperate to intercept boats from north Africa, to detain returnees in Libya, and have established Italian police liaison in Libya (Spruce, 2013).

Refugees and Host Countries

Repatriation became a 'lead' research theme in the 1990s (Wood, 1989; Allen and Morsink, 1994). As early as 1984,

UNHCR had identified repatriation as one of three 'durable' solutions for refugees. The *de facto* solution is long-term integration of refugees in the country of first asylum. The exceptional solution, reserved for only a small percentage of asylum applicants, is resettlement to a third country of asylum. The optimum solution of the three is repatriation – the return migration of refugees from exile to their homeland. The UNHCR proclaimed the 1990s as the 'decade of repatriation.'

Repatriation research focused first on legal or logistical matters, then shifted to the socioeconomic and psychological dimensions of repatriations (Rogge, 1991). Mozambique, Eritrea, and Afghanistan were some of the principal countries of concern. In theory, the repatriation decision is meant to be voluntary, fully informed, and to occur only when the conditions that prompted flight no longer exist. Practically, however, repatriations can involve different scenarios such as refugees choosing to return despite ongoing conflict or being forced to return home by host governments. Forced deportation, or refoulement, of refugees is the worst possible violation of the 1951 Refugee Convention. Deportation or repatriation does not necessarily occur because of a neutral assessment of home country conditions. Refugees may be sent to their countries of origin for a number of reasons, including political and economic pressures in receiving countries.

In Europe, the use of temporary protection visas (TPVs) has been on the rise since the Yugoslav wars and has facilitated deportations. A state's responsibility for a refugee under a temporary protection scheme must be renewed at regular intervals. Such renewal is based on assessment of conditions in home countries. People under TPVs experience a general insecurity, which impacts negatively on their capacity to incorporate into the host society. Once a home country is considered safe, TPV holders may be deported with little notice, often to postconflict societies with inadequate social infrastructure to assist reintegration. Children on TPVs may grow up in a host society and have little or no connection with their 'home' countries to which they are suddenly deported.

In Europe, deportations of failed asylum seekers and of refugees whose TPVs are not renewed appear to be more the norm than is the granting of refugee status. In 2004 in Germany, reports estimated that around 50 000 people were removed, and only 960 granted asylum, and in the United Kingdom, estimates in the same year say that only 4% of asylum applicants receive some form of protective status. The United Kingdom has since also passed a law where those already with refugee status may be deported to their home countries, regardless of their safety there, if they commit a 'serious crime,' the definition of which includes trespassing and possession of drugs. This definition appears to be against the Geneva Convention, which states that refugees may only be deported if they commit 'particularly serious crimes,' what the UNHCR calls 'heinous acts' (Fekete, 2005).

The UK example in particular seems to indicate the precarious conditions of refugees. As outsiders, refugees find considerable difficulty in shifting their status to something approaching permanence. In Amartya Sen's language – he applies it to poor people under conditions of food insecurity – refugees have difficulty in exerting command over the rights that they have as well as the rights that they deserve. In another example, legally recognized refugees in the European Union do not have the same right of free movement as other EU residents. They cannot move out of the country in which they were granted asylum, regardless of the existence of better job opportunities or personal relations.

The majority of the world's refugees are in the South. While refugee situations and treatment in the North are given due attention because of the stark inequalities and contradictions of ostensibly liberal-democratic states treating refugees illiberally, the fact is that most refugees in the South relate to, negotiate with, are governed by, and are sometimes persecuted by a range of different groups. The key difference between refugees in the North and those in the South is that refugees in the South encounter states with weaker machinery. Weakness as regards refugees may sometimes be assumed, a state may portray itself as being unable to provide services for refugees or to prevent discrimination or persecution by nonstate parties, thus restricting their responsibility for refugee well-being.

In a sense, because of the territorial nature of modern politics and the consequence that refugees are strangers in a world of nation-states, there are strong similarities in the way refugees are treated in both the North and the South; the key difference is that in the North external and internal pressures – media or international organizations or a tradition of a democracy centered on a state – are strong enough that the dominant relationship that refugees have is with the state, and – largely – with the institutionalized rules that guide its operation. In much of the South, states do not or cannot control the way their authorities treat refugees. In Malaysia, for example, a paramilitary civil volunteer group, RELA, is tasked with hunting down illegal immigrants, leading to allegations of extortion, use of force, and illegal detention (Human Rights Watch, 2007). The outsourcing of asylum management to RELA also has the consequence of distorting differences between migrant workers and asylum seekers, all classed as potentially 'illegal immigrants.' Some asylum seekers in Malaysia, notably those from Burma, are in 'protracted refugee situations,' where refugees are unable to return to their country of origin, integrate into a host state, or move to a third country. The UNHCR estimate that there are some 6 million refugees in such situations – excluding the special case of Palestinian refugees – most of them in Africa. In a protracted refugee situation, host governments are unwilling or unable to countenance the economic and political implications of settlement. The outsider status that sticks to most refugees tends to gain a harder currency. Refugees tend to be criminalized in state policy and in general public discourse, often with devastating consequences. In Kenya, for example, in the 1990s, the Dadaab camps hosting refugees from Somalia were rife with violence, rape, and murder. Refugees in protracted situations are structurally insecure, their condition of nonbelonging becomes ingrained, protection is either withdrawn or unreliable, and various groups – paramilitary organizations like RELA or bandits around Dadaab – prey on them.

Future Directions

Geographical perspectives on refugees center then on assessing the connections between the movement of refugees and the social spaces through which they move. Allied disciplines, such

as social anthropology and sociology, provide in-depth ethnographic accounts of how refugees are embedded in social, economic, and political relations. Such accounts do not always give a systematic account of space and its production. The contribution of geographical approaches to refugees centers on their capacity to read such relations as active moments of placemaking, of transforming space into territory at different scales and with different degrees of intensity. Geographers connect particular and ostensibly localized acts to wider spatial projects, such as that of territorialization.

Refugee situations are likely to increase in complexity. Three dominant strains, exemplary of broader political and economic structures, are worth pointing out and may prove useful areas for future study. One is the increasing number of people displaced by conflict coupled with the curtailing of their possibilities for flight and resettlement as refugees. EU member states supported military intervention during the 'Arab Spring' conflicts – at least in Libya – and have been vocal in criticizing abuses in Egypt, Tunisia, and Syria. At the same time, EU states have opposed flight from these regions to Europe. Second is the increased number of actors who deal with refugees at the different stages of their movement. One reason for this is the withdrawal of the state, what I have described above as the state assuming or taking on weakness. While largely characteristic of the state in Asia and Africa, state weakness is also evident in Europe at different stages of refugee movement. The formal withdrawal of the state in repatriation procedures in the European Union is telling, with private operators managing the process. A related characteristic is the fragmentation of the state when it comes to assessing asylum claims. Unlike citizens, refugees find it generally difficult to address the entirety of the state. States tend not to be coherent, and political departments and politicians as well as the legislature and judiciary are not necessarily in concert over every issue. Citizens are often able to play with these internal disagreements to try to achieve specific aims. Refugees by contrast tend to be dominated by one specific department of the state – whether the police or an asylum bureaucracy – with little leeway to address or strategically bring into play the entirety of the state. A third strain then is the increasingly blurred lines between asylum seekers, working class migrants, and undocumented migrants. The reasons for these blurred lines are varied, and often depend on specific political and economic pressures or conditions in different host states. The refugeelike experience, existing on the margins of society with comparatively restricted capacity to command rights is an increasingly common condition for poor migrants whether documented or not or whether asylum-seeking or not. In 2011, there were more asylum seekers from Zimbabwe than any other country as individuals sought to flee economic collapse. Only 5% of these asylum-seekers were granted refugee status. The conditions of 'persecution' that lead to flight and to people seeking to resettle elsewhere are varied and the categories of forced or voluntary migrant do not do them justice.

UNHCR's statistics point to increasing numbers of displaced people but declining numbers of people making asylum applications. In 2011, the UNHCR estimates that there were approximately 26 million refugees, including IDPs, but in that year only 876 100 asylum applicants were made. A major issue then is the gap between refugee situations and the capacity of individuals in such situations to enter into refugee assessment procedures. The existing refugee regime does not appear able to address the complexity or magnitude of refugee situations. That regime is structured to manage and contain a potential or existing 'refugee problem,' rather than to help people in flight find abiding security. Geographers can shed light on the difficulties of flight by looking at territorialization mechanisms that work in the first instance to contain a refugee problem. Geographers can also shed light on the complex placemaking activities that obscure refugee situations, or simplify these so that they may be adequately managed by states.

Region: Geographical

Andrew EG Jonas, Department of Geography, Environment and Earth Sciences, University of Hull, Hull, UK

Abstract

The regional idea has long contributed to our sense of living in a world of geographical differences. Even as geographers have championed the concept, they have had profound disagreements about how to approach the region. Early disagreements occurred around the extent to which a region's uniqueness reflected the dominance of the physical environment over cultural factors. Later generations rejected the task of carving up the world into formal regions in preference for spatial analysis. Nevertheless the regional concept has demonstrated resilience even in the face of forces of global homogeneity. Regional scholars today examine regions not as neatly bounded territories but instead as semicoherent territorial assemblages of power relations and economic development processes.

Most people are familiar with the idea that the world can be divided up into geographical regions. Whether based on physical features such as topography, ecology, climate, and vegetation, or human characteristics such as culture, language, and religion, regions still have a great deal of resonance in popular culture, tourism, and the media. Notwithstanding today's powerful forces of global economic and cultural integration, the regional idea continues to contribute to our sense of living in a world marked by geographical difference and diversity. It should therefore come as no surprise that geographers have often championed the concept of the region, regarding it as the discipline's *raison d'etre* in much the same way that geologists think of plate tectonics or economists relate to supply-and-demand curves.

While few now question the value of the regional idea, geographers over the years have had some profound disagreements about how to approach the region. Intellectual schisms initially occurred around the extent to which a region's uniqueness – usually taken as given – reflected the relative importance of environmental influences viz-à-viz human or cultural factors. Subsequently geographers wondered whether carving up the world into formal regions based on their unique attributes was adequate to the task of promoting geography as the science of the spatial. In the 1950s and 1960s, regions were analyzed on the basis of spatial interactions (e.g., trade flows or service-area thresholds) rather than classified on the basis of formal attributes such as climate or culture. Spatial scientists looked to distance the discipline of geography from the regional tradition, only themselves later to be challenged by radical geographers who attributed growing regional inequalities to uneven capitalist development. Nevertheless, regional synthesis *qua* cultural geography clung on well into the latter half of the twentieth century, offering a counterfoil to the quantitative reductionism of spatial science.

In the 1980s, a new generation of critical geographers sought to revive the regional concept. Inspired by neo-Marxist studies of uneven regional development, the new regional geography (NRG) promised to deliver theoretical insights into wider processes of post-Fordist industrial restructuring. It led to a resurgence of the regional concept in geography and closely related disciplines, such as planning and economics, well into the 2000s. Arguing that the uniqueness of regions results from a combination of global and local processes, today's critical scholars no longer examine regions as neatly bounded territories (or scales) waiting to be discovered. Instead regions are approached as semicoherent territorial assemblages wherein wider power relations and networks of governance come together – or fragment – often in contingent and unexpected ways.

Traditional Regional Geography: From Environmental Determinism to Regional Synthesis

In the late nineteenth century, geographers were interested in the role of physical and human factors shaping the form and character of regions. At this stage, geography was influenced by neo-Darwinist views on the relationship between the environment and the development of human societies. Environmental determinism held that dominant racial characteristics reflected the overwhelming influence of the physical environment (Huntington, 1924). The task of the geographer was to identify the presence of such characteristics in a regional population and, in so doing, chart regional boundaries. In the 1920s and 1930s, the Royal Geographical Society in the UK commissioned major expeditions to unexplored regions like the Himalayas, laying the groundwork for carving the world up into formal regions, many still recognizable today. In this manner, the study of human–environment relations prepared the ground for the spread of colonialist systems of governance to remote regions of the world well into the mid-twentieth century.

What gave further legitimacy to the regional idea in geography was the analysis of peripheral regions within Europe at a time of growing threats to empire and the nation state. Early advocates of regional analysis, such as Friederick Ratzel in Germany and Halford Mackinder in the UK, were considered experts in the study of geopolitics. In Germany, Ratzelian geopolitics was soon tainted by its association with the rise of national socialism and racialized visions of regional (viz. national) purity. In the UK, however, Mackinder saw in regional synthesis an opportunity to promote geography and overcome the 'great abyss' between it and the great natural science disciplines of the day such as geology (Livingstone, 1992). What was at stake was the public relevance of the

emerging subject of geography as it struggled to find its niche in the British academy. Later on, in the USA the political geographer Richard Hartshorne developed principles of functional regionalism in order to demonstrate how strong systems of regional planning underpinned national territorial integration and geopolitical statecraft (Hartshorne, 1950).

Environmental determinism eventually gave way to regional possibilism and the idea that human adaptation can be an active response to the constraints of the physical environment. In Germany, Alfred Hettner had proposed the concept of chorology to demonstrate the coimportance of human and physical and human factors in explaining the character of a region (Livingstone, 1992).Yet no single unified view of the region took hold. Instead different traditions of regional enquiry flourished, some barely touched by environmental determinism or functionalism. These hybrid regional approaches sought to achieve a 'true' synthesis of environmental, social, cultural, and economic factors.

Many regional scholars were motivated to study regional life on its own terms. The French geographer Paul Vidal de la Blache referred to this in *Principles of Human Geography* (1926) as a region's *genre de vie* – its particular lifestyle resulting from a combination of natural, social, and cultural factors. Vidal is perhaps better known in Anglo-American geography for *Tableau de la Geographie de la France* (1903) in which he captures what the regional idea represented to France prior to the spread of industrial capitalism. If the main concern was to specify the uniqueness of the region, this somehow also spoke to the uniqueness of the nation. It was essential to Vidal's regional method that the material underpinnings of the region were local and rural even if the effects of long distance trade were clearly visible in the landscape (Wrigley, 1970). Where Vidal's vision of regional geography began to encounter difficulties was when these wider economic and political forces began to transform the cultural–environmental integrity of the region. To paraphrase Wrigley (*op. cit.*: p. 10), the arrival of the canals, railways, and new industries did not simply create a new layer in the landscape which meshed with preexisting layers without disrupting the essential integrity of the latter. Rather it actively destroyed the rural past and so transformed the essence of regional life. Nevertheless, the regional approach continued as a form of descriptive synthesis well into the mid-twentieth century.

Meanwhile, in the United States two very different regional traditions competed for acceptance (Pudup, 1988). These were the Berkeley School of Cultural Geography headed by Carl Sauer and areal differentiation as espoused by Richard Hartshorne. Sauer (1963) viewed regions as organic wholes demanding exhaustive investigation and interpretation through intensive fieldwork. In *The Nature of Geography* (1939), Hartshorne rejected the Sauerian notion that regions exist as cultural organic wholes waiting to be discovered. He sought to show that regions could be defined systematically by showing how their particular component elements, such as relief, vegetation, climate, land use, and so forth, related to other elements. For Hartshorne, regional classification called for a formal process of areal differentiation. Although both perspectives were marginalized after World War II, there were various attempts at revival and rapprochement, which eventually floundered in the rising tide of spatial science.

The New Regional Geography

Criticisms leveled at traditional regional geography became more strident in the 1950s and 1960s. Inspired by powerful new computer technologies and the allure of quantitative methods, spatial scientists turned their backs on regional analysis, regarding it as backward, parochial, and devoid of intellectual rigor (see Johnston, 1991). In light of the alleged superiority of spatial modeling, disagreements over the respective merits of regional synthesis versus areal differentiations seemed out of touch. However, the election of John Fraser Hart as the president of the Association of American Geographers led to a brief attempt to engineer a revival of the regional concept in the early 1980s. In his Presidential Address published in the Annals of the Association of American Geographers in 1982, Fraser Hart memorably made the case for regional synthesis, arguing that "We need a unifying theme that ties together all of the widely disparate phenomena with which we deal, and I know of no other theme that is even remotely so satisfying as the idea of the region. All of the different strands of geography converge when we try to understand a place, an area, or a region … and we need the concept of the region in order to understand why we need the diverse and variegated systematic subfields of geography" (Hart, 1982: p. 18). These sentiments were echoed 3 years later by Pierce Lewis in his Presidential Address (Lewis, 1985). Yet regional geography's eventual savior came from a somewhat unexpected quarter, namely, Marxist-inspired radical geography.

Radical geographers were attracted to regional synthesis because of the need to back up their theories of industrial restructuring and uneven development with empirical evidence. What was at issue was not whether regions could (or should) be formally delimited and functionally classified. Rather the focus of the NRG was on the causes of regional industrial transformation. Specifically, could industrial decline be attributed to some particular characteristics unique to regions or did the causes lie elsewhere in the form of regionally nonspecific processes of deindustrialization and technological change? Doreen Massey (1983: p.75) puts the issue succinctly as follows: "What [is seen] are national processes at work producing the uniqueness of local economic and social structures… [But] the vast variety of conditions already existing at [the] local level also affects how these processes themselves operate." Making use of a geological metaphor, it was possible to argue that regional uniqueness resulted from the interactions between recent 'rounds of capital investment' and the respective local 'deposits' (e.g., labor skills, class structures, products, and so forth) left behind in regions by earlier 'rounds of investment' (Warde, 1985).

The NRG-inspired geographers (along with other social scientists) to conduct detailed study of localities. 'Locality studies' soon became a surrogate term for regional synthesis. However, concerns were expressed that such studies represented a return to empiricism (Smith, 1987). In attempt to deflect these criticisms, proponents of locality studies argued that, unlike past approaches to the region, the NRG was informed at the outset by theories of industrial restructuring. It was important to demonstrate – rather than simply assert – how regional features, such as local labor markets and regional class structures, make a difference to industrial

restructuring, for instance, by altering the relative attractiveness of regions to subsequent rounds of capital investment (Warde, *op. cit.*).

In accounting for the revival of the regional concept, there were respectful references to the Vidalian tradition along with a growing awareness that the NRG itself encompassed diverse theoretical approaches (Pudup, 1988; Jonas, 1988; Agnew, 1990). Besides the aforementioned focus on regional industrial restructuring, the region could be examined as representing a meeting ground between human life-paths and wider social structures under different historical modes of production (Thrift, 1983). Moreover, the NRG portended the revival of the study of nature–society relations. However, this was not a return to a form of crude environmental determinism but rather a growing recognition of human adaption to the limits of nature and of capital. For example, work in political ecology has retained a strong regional environmental focus as it seeks to achieve a critical synthesis of culture, local knowledge, nature, and production (Robbins, 2012: p. 28).

In the meantime, the rural bias of traditional regional geography has given way to a plurality of spatial possibilities, including new economic regions such as the Third Italy and 'edge city' regions like Orange County in Southern California. Alongside environmental conditions, regional economic development processes are now accorded far greater importance in regional transformation in contrast to traditional regional geography's emphasis on culture, settlement forms, and landscape. Capitalist development after mass production seems to be producing not so much a uniformly globalized economy but instead a 'world of regions' based upon specialized clusters of economic activities (Storper, 1997).

A further extension of this theme is looking at how globalization occurs around major city-regions, which in turn undermine the integrity of the nation-state, ushering in a new era of regional resurgence. For economic geographers, such as Allen Scott (2001) and Richard Florida (2008), larger spatial economic units in the form of mega-urban regions (e.g., Greater Tokyo in Japan or Boston–Washington DC in the USA) are today's engines of the global economy rather than older territorial units like countries or Fordist industrial heartlands. Despite the privileging of global city-regions, the nation-state remains influential not least because it allocates public expenditures competitively in support of the infrastructural development of such city-regions (Jonas, 2013). Moreover, the rise of new regionalist social movements likewise points to the profound restructuring of citizenship and democracy from below the level of the nation state.

Future Regions: Relational or Territorial?

The regional idea carries such a bruised and battered baggage in geography that over time concepts like place, scale, and territory have achieved far greater prominence (Jessop et al., 2008). Scholars have even suggested that any attempt to try and 'fix' spatial processes around particular geographical scales like the region are both intellectually redundant and politically naive (Marston et al., 2005). Yet the regional concept remains resilient. To be sure, most scholars shun the idea that the region can be preallocated to a given scale. The endgame in regional analysis is not to produce a map of world regions having fixed and permanent boundaries. Rather the aim is to use the regional concept as a basis for investigating other processes – be these networks, flows, or power relations – and thereby reveal how the specific conjuncture of social relations and spatial structures gives regions their particular territorial form.

As Joe Painter (2008) suggests, regional analysis in geography has for too long suffered from a form of 'cartographic anxiety'; it needs to discard old ideas about drawing 'lines on the map' and think about how regions (however these are defined, materially or discursively) serve wider powerful interests. Regional analysis today involves a very different kind of mapping in which the goal is to reveal how the region represents an assemblage of material activities, social structures, and power relations whose domain is not so tightly bounded by the region (Allen and Massey, 1998). Even if the region tends toward some sort of dominant territorial form (e.g., competitive regionalism), this is merely the visible effect of wider state actions and geopolitical practices. Above all else, contemporary regional approaches seek to distance themselves from single slice-through-time descriptions of the region that characterized geography in the past. Most regional scholars now accept that, irrespective of certain commonly held functional or formal attributes, all regions are fluid and historically contingent social constructions.

In conclusion, one can write about the 'localness' or 'globalness' of a region without assuming that the region occupies a fixed scale between the local and the global. Today's regions have a quality of 'betweenness' (Entrikin, 1991) about them, which means that they cannot so easily be separated analytically from 'other' territories, scales, or spatial structures (Jonas, 2006). Martin Jones (2009) has described the region as a kind of 'phase space' in which various processes may combine either to fix the region around a well-defined territory or contribute to its eventual dissolution. It is in this respect that the regional idea remains intellectually resilient even if the material and social objects to which the concept refers often appear fragile, porous, and semicoherent. That regions continue to differ from one another, not just in their climate and settlement patterns, but also their systems of production can no longer be assumed, as was once the case, but has to be explained in a world governed by systemic processes of global capitalism, varieties of state intervention, and diverse social movements. One can anticipate that geographers shall find many ways of 'arguing with regions' (Agnew, 2013) long into the future.

Abstract

As a field of study, regional geography is concerned with understanding the spatial (regional difference and uniqueness) and temporal (regional change and development) aspects of the increasingly complex world we inhabit. In stark contrast to systematic geography, which is primarily interested in describing the distribution of particular phenomena over the entirety of the earth's surface and uncovering the general rules governing these patterns, regional geography has primary regard for the specificity of regions, places, and locales. As an academic endeavor, regional geography is the backbone of the geographical discipline. Nonetheless, its history is one characterized by ebb and flow, oscillating between periods of strong approval and periods of strong rejection.

As a field of study, regional geography is concerned with understanding the spatial (regional difference and uniqueness) and temporal (regional change and development) aspects of the increasingly complex world we inhabit. In stark contrast to systematic geography, which is primarily interested in describing the distribution of particular phenomena over the entirety of the earth's surface and uncovering the general rules governing these patterns, regional geography has primary regard for the specificity of regions, places, and locales.

As an academic endeavor, regional geography is the backbone of the geographical discipline (Figure 1). In many ways, the history of regional geography reflecting the history of geography – certainly in the mainstream thinking of the twentieth century – has given the former special affinity within geographical circles. This affinity is rooted in understanding how each new branch of modern and postmodern human geographical thought impacted regional geography and concomitantly how advances in regional geography have directly impacted the discipline.

What is important to grasp is despite regional geography being characterized as having a long and distinguished tradition, it is a history which has oscillated between periods of strong approval and periods of strong rejection. This ebb and flow was perhaps best encapsulated by Derek Gregory in his influential book, *Ideology, Science and Human Geography* (1978), where he concluded that:

> Ever since regional geography was declared to be dead – most fervently by those who had never been much good at it anyway – geographers, to their credit, have kept trying to revivify it in one form or another. … This is a vital task. … We need to know about the constitution of *regional* social formations, or *regional* articulations and *regional* transformations.

Figure 1 Schools of modern and postmodern human geographical thought. An increasing variety of schools of thought have emerged over time in the discipline of geography. Source: Peet, Richard, 1998. Modern Geographical Thought. Blackwell, Oxford; p. 10.

Thus, the history of regional geography is marked by a series of rises, each sparked by a new 'big idea' which gains traction to become the foundation for a period of 'popular' approval, and falls, as critics come round to deconstructing – and rejecting – the very idea upon which the success of regional geography at that time was ultimately predicated. The following sections of this article deal with how regional geography continually reinvents itself following periods of rejection.

The Birth of Regional Geography

Although regional geography can be traced back to ancient Greece, the 'classical' period of regional geography refers to the late nineteenth and early twentieth centuries. This was the period when geography became established as a university discipline, with regional geography at its core. Nonetheless, the birth of regional geography as an academic endeavor owes much to events taking place in the eighteenth and early nineteenth centuries when rapid colonial exploration and exploitation of the interior of continents necessitated the need for regionally specific geographical knowledge. This ranged from discovering hitherto unexplored parts of the world, surveying and mapping their features (topography, species, climate), and advising on what new infrastructures were needed to establish and protect commercial and political interests there. Naturalists such as Alexander von Humboldt arguably became the early pioneers of regional geography. Traveling extensively to hitherto unexplored parts of South America–Mexico and Cuba especially – between 1799 and 1804, von Humboldt (together with French explorer Aimé Bonpland) undertook observations which led him to conclude that it was the interrelation of all the physical sciences – climate, topography, geology – which produced distinctly 'regional' geographies.

In German-speaking countries, Alfred Hettner (1927) and Viktor Kraft (1929) followed a neo-Kantian line of argument to identify a new type of regional geography. Kraft, an Austrian, subdivided the discipline into 'general' systematic geography (as a nomothetic science) and 'regional' geography (as an idiographic science). Similarly, in Germany, Hettner argued geography must deal with both the unique (regional geography) *and* the universal (systematic geography), but as a chorological science the study of regions must occupy a pivotal position at the core of the discipline.

Meanwhile in the United Kingdom, the Geographical Society of London was established in 1830 (becoming the Royal Geographical Society in 1859) for the stated purpose of the 'advancement of geographical science.' This was allied to 'colonial' explorations principally in Africa, the Indian subcontinent, the polar regions, and central Asia. As well as funding expedition, the Society was also responsible for incorporating the study of (regional) geography in schools and for the first university positions in the discipline at the turn of the twentieth century.

Empire and Environment: The Traditional Regional Geography

The very essence of 'traditional' regional geography was the connection to empire and the environment. It was also characterized by environmental determinism, a period bookended by Charles Darwin's *On the Origin of the Species* (1859) and Richard Hartshorne's *The Nature of Geography* (1939) (see **Figure 1**). The period of traditional regional geography was also the first example of the rise and fall of a dominant orthodoxy – environmental determinism – in (regional) geography.

Traditional regional geography can be divided into three main schools of thought: environmental determinism, possibilism, and cultural traditions. Environmental determinism, geographers' shared conviction that there was direct connection between the nature of the physical environment and the historical activities of man, gained approval as (regional) geography's first 'big idea.' Oxford professor and head of the first UK Geography Department, Halford Mackinder's *Britain and the British Seas* (1902) codified how patterns of war, skills, and the evolution of race are all determined by 'natural features.' Brought to Oxford by Mackinder, Andrew Herbertson (1902) went further, arguing that above all other natural features it is climate that has the greatest influence on man and his work (sic) and proceeded to identify 'natural climatic regions.'

In France, Paul Vidal de la Blache offered his own very influential analysis that allowed for 'possibilism.' Vidalian regional geography does not deny that there are natural limits to human activity but recognizes the significance of humanity's choice of activity as opposed to the natural limits of it. In this way, it is unreasonable to pursue a regional geography which is determined only by environmental factors. For Vidal and those he inspired, the natural landscape cannot be separated from the cultural landscape. Moreover, the two influences – natural and cultural – fuse through regions to produce distinct 'pays' (regional landscapes) and 'genres de vie' (regional lifestyles).

Meanwhile back in the United Kingdom, Herbert J. Fleure injected an even greater interest in human experience into (regional) geography. Rejecting Herbertson's determinist approach, Fleure contended that regional geography owed more and more to the outcome of human activity, especially the exchange of cultural influences as people became less rooted in place. In line with this view, Fleure (1919) proposed 'human regions' and alongside Carl Sauer (Berkeley, California) and Paul Vidal de la Blache (Paris) founded geography's cultural tradition (see **Figure 1**).

Regional Geography as a Science

During the interwar period Anglo-American geography was forced in reinvent itself to uphold its status as a credible scientific discipline. The demise of environmental determinism meant regional geography lacked a 'big idea' while its position as the science of empire was of diminishing use when the major empires were in decline. Regional geography as the science of empire and environment consequently lost ground to emergent, 'scientific,' and 'relevant' disciplines such as economics, sociology, and meteorology.

Richard Hartshorne's *The Nature of Geography – A Critical Survey of Current Thought in the Light of the Past* (1939) represented geography's response to these challenges. Inspired by

Alfred Hettner's (1927) neo-Kantian argument, Hartshorne contended that what made geography 'exceptional' – and therefore useful vis-à-vis other scientific disciplines – was that at its core it was a 'regional' discipline. As the title and subtitle of his book both imply, Hartshorne's approach involved going back to the origins of regional geography to reaffirm geography as the study of what makes some places (or regions) similar and others different. In doing so, he prioritized geographer's use of idiographic methods to deal with the particular and the unique. For Hartshorne, geography was ultimately a study of 'synthesis,' where each region is a unique area defined and distinguished from others by being the product of a distinct blend of systematic geographical factors. Emphasizing the individuality of regions, this type of geography became known as the study of 'areal differentiation.' Perhaps unsurprisingly, attention would often be drawn to the uniqueness of regions, but as Hartshorne himself stated, his approach to regional geography required investigating both similarities and differences over space:

> Three major steps are involved in a study in regional geography. In order to comprehend the actual interrelation of phenomena in specific places it is necessary to consider small subdivisions within each of which the local variations of the various factors are arbitrarily ignored. The second step is to relate the unit areas to each other to discover the structural and functional formation of the larger region. Finally it is necessary to study the arrangement of the regions to each other and the interrelation of phenomena in one region to those in another.
>
> 1939: xv

In the United States especially, the study of areal differentiation was to provide a period of relative calm and stability for the geographical discipline. This was to all change, however, in the 1950s and 1960s. At this time geography's claim to exceptionalism came under sustained attack from a rapidly expanding nomothetic paradigm which was to give rise to regional science and quantitative-spatial geography (see **Figure 1**).

In *Exceptionalism in Geography: A Methodological Examination* (1953), German-born Fred K. Schaefer produced a withering critique of the Hartshorne-inspired practices of regional geography. Practitioners of regional geography were accused of engaging in unscientific working practices, of producing nothing more than woolly empiricist 'descriptions' of phenomena that lacked any theoretical foundations on which an analytical 'explanation' for their empirical evidence could be grounded. As the title implies, Schaefer's article courted controversy in directly attacking the Kant–Hettner–Hartshorne view on what made geography 'exceptional.' A controversy not averted by Schaefer's death prior to the article appearing in print, his piercing academic critique was to pose a serious threat to the regional tradition. At one level, and despite ripostes from Hartshorne (1959) it effectively killed off traditional regional geography as an idiographic discipline. At another level, it argued that for geography to survive it must establish itself as a nomothetic (law-producing) discipline by using the hyptothetico-deductive scientific method.

The law-producing regional geography that emerged in the 1960s owed much to the 'locational school' and its alliance of economics with geography (and planning). In the United States, Walter Isard (1960) was the forerunner in constructing a 'regional science' to counter the a-spatial classical economic theory of the German location school (Johann Heinrich Von Thünen, Alfred Weber, August Lösch, Walter Christaller). His alternative approach sought to move beyond 'explaining' location simply by cataloging geographical factors to a more sophisticated 'analysis' that attempted to fuse these factors together in regional input–output techniques (linear programming). Regional science flourished in the 1950s and 1960s as a nomothetic discourse asserted itself as the mainstream methodological approach in Anglo-American geography. Allied to developments in the United Kingdom, most notably Peter Haggett's (1965) seminal book, *Locational Analysis in Human Geography*, the quest to identify general ('scientific') laws to explain spatial behavior led to a decline in intensely place-based (regional) studies in this period. Yet regions, and regional geography, survived because although regions were often deployed uncritically as spatial backdrops on which human activity took place, in this role they proved to be "one of the most logical and satisfactory ways of organizing geographic information" (Peter Haggett et al., 1977).

By the 1970s regional geography had been pushed to the margins of geography. One commentator went so far as to say that regional geographers should be considered the 'last of the handloom weavers' (John Paterson, 1974) – a group of diminishing relevance, too commonly found looking back to the halcyon days of traditional (regional) geography, and crucially, seen to have little or no contribution to make to a discipline increasingly captivated by developments emerging from a new generation of critical geographers and splintering into new subdisciplinary fields to incorporate new approaches to understanding the spatial construction of social processes. Indeed, despite John Fraser Hart (1982) hailing regional geography as "the highest form of the geographer's art" owing to the rich descriptive narrative a focus on traditional approaches facilitates, it was the emergence of radical Marxist geography and its critical perspectives on the geographies of uneven development that was to prove the torchbearer for a reinvigorated regional geography in the 1980s (see **Figure 1**).

Reinvigorating Regional Geography: The Emergence of 'New Regional Geography'

Regional geography experienced a renaissance in the 1980s owing to two principle developments. On one level, regional geography benefited from the failings of the positivist mode of explanation. Having effectively de-humanized geography by overlooking the active role people play in shaping social processes and practices, the criticism of the nomothetic paradigm in mainstream geography – alongside the crisis of 'grand narratives' of humankind (communism, religion, science) and 'grand theories' in the academic world – saw increased pressure placed on totalizing discourses and led to a reawakening of interest in the special/specific (idiographic). Affectionately referred to as 'the mother' of the new regional geography (Markusen, 1993), Doreen Massey (1984: 51) was one of a growing number of academics to point out how regional

specificity had been firmly reinstated on the methodological agenda:

> … [G]eography matters. The fact that processes take place over space, the facts of distance or closeness, of geographical variation between areas, of the individual character and meaning of specific places and regions – all these are essential to the operation of social processes themselves. Just as there are no purely spatial processes, neither are there any non-spatial social processes. … Geography … is not a constraint on a pre-existing non-geographical social and economic world. It is constitutive of that world.

On another level, a more critical scholarship emerged through the coming together of previously isolated academic approaches – the political-economic, humanistic-phenomenological, and structurationist/critical social theory (cf **Figure 1**) – each seeking common ground through a 'geography of regions.'

The political-economic approach is rooted in Marxist analyses of uneven 'regional' development. It focused on the ways in which regions were seen to be increasingly central to the shifting geographies of capitalism. Following the crisis of the nationally scaled Fordist mode of production and Keynesian regulatory system in the 1970s, the switching and displacement of the crisis tendencies of (global) capitalism into compensating regional configurations provided a significantly new perspective on the region (David Harvey, 1982). Regions were no longer considered to be just a spatial backdrop against which developments occurred but the specific sociospatial, historically contingent context that produces different pathways of capitalist development (Doreen Massey, 1984). Hence, regions are not fixed and easily mapped (as in regional science), but relative and constructed in different ways (in this case, according to the shifting economic geographies of capitalism).

The humanistic-phenomenological perspective adopted a similar position, albeit regions are relative and constructed based on attachment to particular places and regions. Harking back to the Vidalian tradition, regions are a focus of cultural identification (or 'sense of place,' Doreen Massey, 1991) and are constructed through identity formation. In direct opposition to the positivist tradition underlying regional science – where human activity was determined as rational and could therefore be predicted and planned for – the humanist approach placed the intentionally acting human being at the center of their academic inquiry in order to understand the attachment (and sense of belonging) people have to their spatial environment (place, region). Here the emphasis was again placed on understanding regions as historically contingent process, never static but always in a state of formation, reformation, and/or transformation (Allan Pred, 1984). Also important was the analytical distinction made between place, as personal experience structured through one's own individual biography, and region, which embodies a collective dimension of shared experience (Annsi Paasi, 1986).

Derived from Anthony Giddens' (1984) theory of structuration which sought to overcome the traditional binary division between 'structure' and 'agency,' the structurationist perspective is chiefly characterized by consideration of the region as both 'outcome' and 'producer' of social practice. Collectively, the new approaches to understanding the region were thus seen to differ significantly from traditional conceptions because society was included as a key agent in region formation. In short, claims of the birth of a 'new regional geography' were seen to be warranted as the traditional concern with the people–nature relation gave way to the triangular relations between people, society, and nature at this time (Anne Gilbert, 1988). What is more, with the individual and history at its core, this new reconstituted regional geography emphasized the need to understand how regions are socially constructed across space and time. Work in this area is perhaps best showcased by two distinct, yet related, approaches.

According to the Finnish geographer, Anssi Paasi (1986), explaining region formation requires an understanding of regional institutionalization. Regional institutionalization results from the coming together of historical, economic, political, and social processes to produce a specific (and always contested) cultural image. To understand this, Paasi argues that the institutionalization of regions is a process comprising of four interdependent stages: (1) the development of territorial shape (as practices and processes become localized and territorialized); (2) the formulation of conceptual or symbolic shape (e.g., flags, anthems) to establish and reproduce a regions identity; (3) the emergence of institutions (e.g., education, media) to deepen regional practices in politics (e.g., regional government), administration (e.g., regional offices), and culture (e.g., regional events); and, which lead to (4) the establishment of a region in the spatial structure and social consciousness of society.

The impact of this thinking also posed a more substantive methodological challenge for regional geographers. For as John Allen et al. (1998: 2) put it in the context of their own attempts to determine when was, and where is, the southeast region of England:

> Regional studies are always done for a purpose, with a specific view. Whether territorial, political, cultural or whatever, there is always a specific focus. One cannot study everything, and there are always multiple ways of seeing a place: there is no complete 'portrait of a region'. Moreover, 'regions' only exist in relation to particular criteria. They are not 'out there' waiting to be discovered, they are our (and others') constructions.

The new regional geography was therefore more complex, dynamic, and contested than its predecessor, characterized not by a singularity of approach but a plurality of different approaches, each seeking common ground through a (re) new(ed) geography of regions.

From the mid-1980s through to the early 1990s the new regional geography proved fertile terrain for a fairly intensive conceptual debate. Nevertheless the plurality in (conceptual, empirical, philosophical, methodological) approach made it difficult to sustain the new regional geography as a coherent academic endeavor. At one level, academic fatigue began to set in as scholars exhausted certain lines of inquiry and significant steps forward became less common. At another level, inherent shortcomings were being exposed. On the front line for criticism was the major research program on 'localities.'

Inspired by the work of Massey (1984), localities research set out to examine the economic consequences of global capitalist economic restructuring on specific places and regions.

Yet it was not localities as the outcome and producers of spatial processes which were to be understood but social interaction within the boundaries of predetermined study areas ('localities') that left localities research open to such piercing critique (*Antipode*, 1987–91). Add to this further criticism that localities research came dangerously close to returning regional geography to 'exceptionalism' (by systematically failing to engage theoretically or conceptually), never fully defined and grasped the usage of its key concept and term ('locality'), and focused too narrowly on economic factors alone to account for place formation; it is perhaps not surprising that in the face of growing criticism many of those scholars who came together in the 1980s to enthusiastically pursue new academic endeavors through a geography of regions dispersed to pursue other lines of inquiry in the early 1990s rather than undertake the renewal necessary to keep the new regional geography alive.

As the new regional geography started to wane, a new brand of regional geography emerged to reignite enthusiasm for a further shared academic endeavor – the 'new regionalism.'

Regional World(s): The Rise of New Regionalism

The new regionalism rose to prominence in the 1990s as regional geography's latest 'big idea.' Contrary to popular belief held throughout the 1970s and 1980s that globalization was bringing about deterritorialization and an era of global deconcentration (a 'borderless world'), the new regionalism came to represent the realization that for all that globalization was extending our capacity to interact more freely across space, geography still mattered. More substantively, regions were seen to challenge – even replace in some accounts – the nation-state as the prime territorial unit for organizing and structuring economic, social, and political activity in an era of (neo)liberal globalization. From this perspective not only did geography matter, it was a regional geography that appeared to matter most.

Despite interest in the new regionalism centering on a shared endeavor to explain the resurgence of regions in globalization, just like the new regional geography which preceded it, the new regionalism does not exhibit a uniform approach toward method. There are basically two empirical approaches, divided according to whether the research pursued was rooted in the 'geoeconomic' or 'geopolitical' logic for the reemergence of regions.

The Geoeconomics of Regions

One distinctive feature of the new regionalist debate is the realization that localized ('regional') agglomeration economies appeared to foster the conditions, harbor the assets, and generate the capacities upon which increasingly globalized, transnational capital accumulation depended. In this way it formed part of a broader economic development discourse synonymous with accounts documenting how, for all globalization was producing an era of global deconcentration – as capital was freed from the shackles of historically entrenched nationally scaled Keynesian regulatory systems – globalized capital accumulation was increasingly found crystallizing out on the ground in a select number of strategically important local urban and regional production complexes. First among many were the new industrial regions of Silicon Valley and Route 128 in the United States; and Baden-Württemberg, Catalonia, Lombardy; and the Rhône-Alpes, the so-called 'Four Motors of Europe.'

Bucking the trend of national economic decline these new industrial growth areas of the post-Fordist economy became poster-regions for ascendant 'new regionalist' orthodoxy. Constructed around a conjecture that there was something absolute that connected late twentieth-century capitalism to regionalism and regionalization, proponents of the new regionalism appropriated a strong geoeconomic logic for explaining why the post-Fordist growth dynamic was rooted in regional (not national) economies (Michael Storper, 1997). First, economic success is not exclusively related to a narrow set of economic factors but is dependent on social, cultural, and institutional structures. Second, these noneconomic factors see information sharing, collective learning, and the build-up of 'social capital' (e.g., trust, loyalty) replace market-based competition as the basis for economic success and competitiveness in an era of reflexive capitalism. And perhaps most crucially, third, regions (not nations) are the most appropriate scale for spatial clustering, networking, and interaction to take place.

After a fairly intensive period of theorization in the mid-1990s the geoeconomic logic underpinning the resurgence of regions began to capture the mainstream interest of political leaders and policy elites. This led to the formation of a new global policy discourse predicated on a new regionalist orthodoxy broadly claiming that contemporary capitalism and its territorial configurations are best regulated and governed in and through the decentralization of socioeconomic decision-making and associated policy implementation to regional level institutions, frameworks, and supports.

The Geopolitics of Regions

As fundamental to the new regionalist orthodoxy as the strongly appropriated geoeconomic logic is the geopolitical logic which accounts in part for this resurgence of regions in the latter decades of the twentieth century. At the same time a group of primarily economic geographers uncovered new successful forms of production in local industrial districts and selected regional economies which led them to reframe the geographies of the global economy, a coterie of political and cultural geographers (alongside a group of political scientists) observed how a reigniting of interest in nationalist and regionalist territorial identities, politics, and citizenship was reworking the established landscape of contemporary politics and cultural expression. Broadly speaking the geopolitics of regionalism derived from two sources. First, there was the reemergence and affirmation of traditional cultural insignia to distinguish one region from another in an era where American hegemony was seen to threaten erase traditional regionalist and nationalist identities and cultures from the political landscape. Meanwhile second, there was strong political reaction from within national states against the authority of national government's following the failure of the central state to adequately manage and protect the Fordist mode of capital accumulation and Keynesian regulatory system which sparked

calls for the transfer of power to economically advanced territories (e.g., Baden-Württemberg, southeast England) and/or historic territories with separatist movements (e.g., Catalonia, Lombardy, Quebec, Scotland).

The most striking characteristic of this is the way in which the need to distinguish regions from one another resonated with the very essence of the origins of ('traditional') regional geography as the study of what makes regions unique and distinctive. Nevertheless, the more substantive point was actually the placing of regional geography at the center of debates on a purported 'scalar turn' in social scientific thinking. The interest of geographers was arrested by claims the nation-state was being economically and politically challenged by the 'regional state' as a potential successor to its long-held authority as the site and scale at which the economy is managed, social welfare administered, and people are treated as citizens (Kenichi Ohmae, 1995).

The impact of this thinking was particularly evident in Europe, where the rise of regions and regionalism from the 1970s onwards prompted construction of the popular 'Europe of the Regions' discourse which by the early 1990s had advocates suggesting the formation of, and transition to, a federalized European superstate. Yet it was to be the more considered analyses produced at this time that recognized that regions were not replacing the nation-state per se, rather they were becoming competitive and strategic territories within an emerging multilevel system of capital accumulation and governance extending from the global to the local. What this gave rise to was a regional geography heavily focused on the study of state–region relations.

The Critique

There can be little doubt that the new regionalism proved a fertile terrain from which regional geographers were able to once more reassert the central importance of regions to the geographical discipline. But just as with each of regional geography's big ideas that went before, the new regionalism came under intense scrutiny when John Lovering's (1999: 380) contention that proponents of this orthodoxy were narrating an "attractive and persuasive story, but it is largely a fiction" laid bare its inadequacies. Chastising many of those engaged in new regionalist theorizing as guilty of bad abstraction, Lovering raised concern over the exclusive nature of the empirical referents used to construct new regionalist orthodoxy. What is more, in developing this line of argument Lovering was to demonstrate how many proponents of the new regionalism lost sight of the fundamental characteristic of regional geography ('specificity') in the hot pursuit of theorizing regional development as something which is generic and therefore lends itself to be understood in more abstract terms.

Rays of regional sunshine set against an increasingly overcast national economic outlook, on first view it is not surprising these regional industrial production complexes were lauded for spearheading the economic recovery, providing a template for achieving global competitiveness, and being drivers of the national economies within which they were situated. The 1990s was a time when the search for a new post-Fordist, post-Keynesian, post-national blueprint for organizing capitalist development was at its most fervent. That new regionalist accounts appeared to provide such a blueprint catapulted those engaged in new regionalist theorizing to the forefront of academic, but also increasingly political, debate. Captivated by accounts detailing the geoeconomic factors underpinning the growth of Silicon Valley, Baden-Württemberg, and Emilia Romagna, policy elites the world over where mobilized by the belief that the new regionalist consensus provided the policy recipe which would enable them to position their region(s) within national and international circuits of capital accumulation. Furthermore, policy elites mobilized with speed in the knowledge that not only did they need to intervene to create the conditions necessary for capital accumulation, they needed to make their region(s) more attractive to transnational capital than their national and international competitors to be competitive in today's quicksilver global economy.

The problem observed by Lovering was that sophisticated theorizing of actual economic developments and observable outcomes in these prototype regions were to be silenced by more speculative theorizing based on assumptions celebrating what they hoped might be possible in an idealistic scenario. In what he famously referred to as the "policy tail wagging the analytical dog," Lovering detailed how the ensuing period of intense institution-building became the focus of new regionalist theorizing, such that what started out as a warranted academic endeavor to understand the dynamics of regional development was lost to an unwarranted orthodoxy fueled and sustained not by on-the-ground realities, but because they resonated with policy elites who wished to explore the scope for policy interventions at the scale of regions. In a self-perpetuating way, successive rounds of policy intervention at the regional level were purported as evidence of the growing importance of regions as strategic sites in globalization, which in turn fueled the political appetite to explore the scope for further policy initiatives at the regional level.

Where Next for Regional Geography?

Explaining regional change remains one of the great challenges for the social sciences, and geography in particular. Yet as Nigel Thrift (1996) once observed "[o]nly a very few human geographers nowadays would lay claim to being 'regional geographers', and in quite recent times regional geography has been described as if it was in need of exhumation rather than resuscitation." Nearly two decades on regional geography continues to survive. Its prominence is sustained not simply by the constant renewal of ideas, approaches, and perspectives required for any discourse, paradigm, or subdiscipline to evolve and survive for a significant period of time but by a series of major reboots. The history of regional geography is thus dominated by periods where a new discourse or paradigm is first constructed, only to be challenged, damaged, deconstructed, dismantled, and condemned, before then being rebooted, revived, reconstructed, only to be rechallenged (…and so the cycle continues) and where the highs are very high and the lows appear very low.

Notwithstanding the longevity of regional geography within geographical and social scientific debate there remain a series of unresolved issues. To begin with there is the ontological status of its foundational concept and object of inquiry – the region.

Over the years, the region has been variously referred to as an 'embattled,' 'chaotic,' 'mysterious,' and 'vague' concept. The problem is that much work which is purporting to be regional geography fails to adequately define the region to which they are either referring, or are working with. Where this occurs the region is often assumed, thereby failing to recognize the 'multiple ways' of seeing a region (Allen et al., 1998).

This problem relates to another unresolved issue: regional geography does not exhibit a uniform approach to method. Work in regional geography can be categorized as adopting one of three approaches: historically reinterpreting regional developments which have taken place, interpreting regional developments taking place in the present, and projecting regional developments which will take place in the future. This contributes to methodological pluralism which is a defining characteristic of regional geography. More significant than this, however, is the relationship between theory and empirics. This has been at the root of all the episodic rise and fall in regional geography's long history. To illustrate this point we need only look back over the past 30 years at the locality debate and the new regionalism. Focusing exclusively on the locality and region respectively, the theoretical abstraction from empirical description of what appeared to be working in a number of locations often excluded important external factors – national and global political-economic trajectories, the changing role of the nation-state, transnational corporations – which clearly had a major impact on shaping local and regional development. What this points to is a broader challenge which regional geography constantly confronts: the interaction between empirical observations of regional difference ('description' on what is exceptional) and theoretical abstraction ('explanation' of what is typical).

Despite these unresolved issues, the prospects for regional geography ultimately hinge on the ability of its proponents to ensure regional studies remain socially relevant in our increasingly globalized modern world. Indeed, there are a number of new horizons in regional geography which are providing the context for the next generation of regional research.

Theoretically, one of the outstanding arguments centers on the 'regional world(s)' we live in and how best to capture the dynamics of contemporary regional development and change (Martin Jones and Anssi Paasi, 2013). Singular understanding of regions as territorially bounded, homogenous units have by and large been rejected and replaced by relational approaches that view regions as being constructed through wider, 'stretched' social relations. Although this contributed to a back and forth exchange between proponents and engaged critics of the relational approach over the last two decades, this is now being superseded by new conceptual interpretations which consider how different spatial dimensions – territorial, relational-networked, place-based, scalar – actually come together to form complex space-time ('regional') configurations. Singular understandings are thus being replaced by a more plural approach to understanding contemporary societies, with the fusion of the different approaches often animated through a renewed geography of the region.

Socially, there are also a series of turning points which are not only exerting pressures on global society but whose impacts are likely to be highly regionally uneven. The first turning point is the 2008 global financial crisis and ensuing economic crisis. This has already had a major short-term impact on regional development schemes following the withdrawal of credit, but longer-term the cycle of debt repayment and austerity packages will be a serious obstacle to growth and a major impact on public finances. Alongside this the effects of climate change and related pressures in terms of the availability of water, energy, and food are also likely to be highly regionally uneven. Given this, attention has been directed toward consideration of which regions are most/least resilient to these external pressures (Ron Martin, 2012).

Spatially, a deepening of global economic integration alongside accelerated processes of urbanization is having a major impact on the construction and configuration of regions and regional space. One consequence of this was witnessed at the beginning of this century when the new regionalism morphed into a more urban-centric discourse of 'city regionalism.' Purported to be pivotal, societal, and political-economic formations and signifiers of a new phase in capitalist territorial development, one of the dominant characteristics of this focus on globally significant major urban regions is the trend toward identifying ever larger regional spaces. Nowhere is this more evident than in the recent focus on 'megaregions' (Richard Florida et al., 2008) which raises a host of important questions relating to how far the regional concept can be stretched, how plausible it is to conduct empirical research at markedly different regional scales, and what (if anything) marks these spaces out as regional.

All of these unresolved issues and challenges pose searching questions that get to the root of what it means to do regional geography. But it also provides fertile terrain for contemporary regional geography to explore and develop.

Regional Planning

Abstract

The case for regional planning turns on the logic that a strategic overview is required to deal effectively with urban and environmental issues that have wide implications. This includes, but is not limited to, transport planning, the management of environmental assets and the location of housing developments. In this article, the authors set out the history of regional planning, contrasting the ways in which the term has been employed in diverse national settings before going on to chronicle the suite of activities that have at various times comprised the activity of regional planning. The authors conclude by taking stock of the position occupied by regional planning in some states at the end of the first decade of the new millennium and ask what turn regional planning will take next.

Introduction

At root, regional planning is about situating the decision-making processes relating to traditional planning activities – transport, housing, environmental impact assessment, and so on – at a strategic scale. In this sense, the 'regional' of regional planning is a byword for a scale of governance at which a wider, more holistic approach can be taken to the management of the urban and natural environments. However, discussing regional planning is problematized by ambiguities in this concept at the core of the expression: what is meant by a 'region' depends fundamentally upon where you are. To the US-ear the idea perhaps speaks most clearly to the idea of governance in or for a metropolitan region (Greater Portland, for example), although this should be clarified to include the origination in the North American context (Gottman, 1961) of the mega region, which might itself be constituted by smaller regional territories not necessarily tied to one specific metropolis. By contrast, in Europe the region is more usually understood to be a constituent subnational territory of varying political status: sometimes a systemically formal component of a federal polity (such as the German *Länder*); occasionally a semiformal territory as with the regional state apparatus devolved to the English regions by the British government in the late 1990s and 2000s; or an informal, tacit recognition in national policy making of centuries-old regional identities built on differences of language, culture, identity, and politics.

Building from this patchwork of various regionalisms nuanced accounts have resulted in an understanding in the West of fluid subnational spaces that might, depending on context, be described as regions, city-regions, or polycentric regions (Davoudi, 2003). In parallel, a different vernacular has emerged elsewhere with the 'mega city' (Hall, 1999; see also, Lin and Ma, 1994; McGee and Robinson, 1995) describing in China and India (see the article 'Regional Planning: China in this encyclopedia) what would probably be thought of as akin to a metropolitan mega region (in the United States) or a European city-region – albeit often on a much grander scale. These differences of scale and size add further complexity to the issue with attempts at creating statistically standardised regional entities, such as the NUTS-3 classification popular in continental Europe, grating against wildly different qualitative scalar understandings of what a region might be ranging from, for example, small Japanese prefectures to the huge oblasts of Russia.

Whilst this discussion of international variation in nomenclature reveals semantic differences perhaps more importantly it illustrates the global significance of a territorial scale, whatever we might call it, between the nation-state and city hall at which academics, policy makers, and business leaders have found it sensible to think about the organization of social, economic, and political life with corresponding implications for the natural and built environments. As a consequence, the vast majority of national governments have at some point in their history chosen to include a regional tier of strategic planning as part of their approach to urban and environmental management: although with differing remits and intentions for what regional planning should seek to achieve from time to time and place to place. In this piece, we set out to provide an overview of this evolution of regional planning in both theory and practice before asking what turns regional planning might take next.

Regional Planning in Historical Focus

Although the practice of acknowledging and responding to regional differences as part of the act of governing heterogeneous societies can be traced back to the ancient world (the Roman Empire being a good example, see Nicolet, 1991), Wannop and Cherry (1994) date the origins of regional planning as a component of a modern statutory planning system to the more prosaic setting offered by South Wales in the United Kingdom. Here, in 1921, a government committee was appointed to consider housing, transport, and the provision of utilities to the area's large coalfields. The committee's report advocated considering the area to be what one might now understand to be a functional economic region comprising 15 individual administrative units. While the proposal was rejected by central government, the idea – the germ of which can be found earlier in Howard (1902) and Geddes' (1915) great early statements of town and

country planning – took hold and can be seen as the genesis of a form of planning for metropolitan regions in cities such as Manchester, Birmingham, and London in the 1920s. The resultant Joint Town Planning Committees as the name implies acted as strategic planning bodies for these cities together with their hinterlands (Hall, 1974).

This concept of planning for metropolitan regions established in the 1920s was reinvigorated following the end of the Second World War and formed a central plank in Britain's postwar reconstruction with many plans from the period taking on an explicitly metropolitan-regional dimension, good examples being the Clyde Valley Plan (1946) and the Greater London Plan (1944). Parallel processes can also be identified in the emergence of strategic regional planning in other Western European contexts at the same time, for example, France (Boudeville, 1966; see also Hudson and Lewis, 1982) and Germany (Brenner, 1997) where the federal system of government invested regions with formal political power and responsibility for developing regional planning policy. Furthermore, the flavor of European regional planning in the aftermath of war came to reflect the politics of the time effectively providing a territorial counterpart to a broad societal consensus built on the twin pillars of social democratic politics and Keynesian macroeconomic policy. A focus on spatially balanced growth, planning new settlements, and demand stimulation in less prosperous regions came to be a core feature of postwar regional planning in Britain and its continental neighbors.

In turn, the diffusion of the concept from Britain to other countries in the Commonwealth such as Canada (Cullingworth, 1987) and Australia (Collits, 2012; Freestone, 2012) gave the idea of regional planning wider international currency. However, the application of 'regional planning' in these settings served primarily to illustrate the malleability of the concept. When overlaid onto the federal system of government in these much larger, more sparsely populated nations, the idea of planning at a regional scale came to inhabit multiple meanings bound up with contextual differences of governance, urban–rural interdependencies/rivalries, and resource allocation. Moreover, the scale at which this form of regional planning took place often spanned territories that dwarfed the original European understanding of what a 'region' could be. The result was a qualitatively different understanding of how regional planning should proceed even between nations in which regions enjoyed the privileged position of being a formal state space, although the kernel of the idea that 'standing back' and taking a strategic, long view remained common.

Elsewhere, this same logic of aligning regional with 'strategic' planning was at work but with quite different effects. Rather than regions representing an amplification of established planning activities overlaid onto preexisting, fractured local authority geographies, in contexts such as the US policy makers looked beneath the formal tier of government offered by the federal state to explore new spatial configurations. Often, the result was the identification of a mega region, such as Southern California, encompassing many cities together with hinterlands boasting important environmental assets. Sometimes, these mega regions subsequently came to be understood as having constituent functional regions within them – for example, 'coastal' and 'desert' in the case of Southern California. The corresponding emergence of planning agencies for these mega regions grew up in parallel to the first identification of this scale as of strategic importance in the early 1960s. For example, again using the same example from the United States, the Southern California Association of Governments has, since 1965, sought to provide a coordinated governmental response to planning issues, such as transport, across a huge territory at the time of writing now encompassing six counties and 191 cities (SCAG, 2013). Moreover, there is evidence to suggest that the identification of US mega regions and the emergence of a state architecture to represent them has been followed by a nascent form of mega-regional identity; for instance, the use of 'SoCal'/'NoCal' to denote an identification with, respectively, Southern or Northern California, has permeated the popular consciousness and is routinely used as a commercial branding device (of clothing, bumper stickers etc.) on the West Coast of the United States.

Academic Interest in Regional Planning and Its Challenges

The resulting impression is that regional planning, as a highly variegated and context-specific set of practices across the globe, is probably best understood as a child of the early twentieth century, symbiotically connected to the rapid and profound social changes brought about by the innovations of that century: mass automobile ownership, commercial aviation, and the 'agricultural revolution.' In the academic world, the differing territorial effects of these wider social and economic trends spawned interest in the challenge of coordinating agencies tied to what had fast become antiquated administrative boundaries and providing an even level of service provision to cities with rapidly increasing urban populations and porous boundaries. Some of these issues had earlier been forecast by the forefathers of planning as being an academic discipline. In this respect, Geddes' (1915) *Cities in Evolution* is often credited with awakening academics to the analysis of the wider (literally, in a spatial sense) implications of social, environmental, and economic changes brought about by Western urbanization (for a review see Glasson and Marshall, 2007). Seminal contributions followed (e.g., Friedman and Alonso, 1964), which in turn spawned a welter of academic interest on all aspects of planning viewed through the prism offered by the region to the extent that by 1979 it was said that "regional planning has come of age" (Friedman and Weaver, 1979: p. 1).

In retrospect, these claims of intellectual maturity may have been precipitous. Glasson (1992: p. 505) identifies a subsequent wane in interest in regional planning from around the time Friedman and Weaver (1979) date its ascension: "from the late 1970s to the start of the 1990s, regional planning was in the doldrums." This decline is perhaps best explained by a shift in academic focus in two directions – to the 'world' or 'global' cities of, for example, London, Los Angeles, New York, Paris, Tokyo (Knox and Taylor, 1995; Sassen, 2001), and the 'shrinking cities' (e.g., Detroit, Leipzig, and Manchester) where postindustrial economic restructuring had left the scars of population loss, unemployment, and social atomization (e.g., Bontje, 2004; Mace et al., 2005; Ryan, 2008). Subsequent years saw academic interest in regions return partly as a result of the

effects of economic globalization and the apparent importance placed by some of the largest transnational corporations on regionally significant variables – such as concentrations of specialist labor – in making their location decisions. The spatial effects of these economic processes were said to be a "pulling up, pushing down, squeezing sideways" (Giddens, 1998: p. 13) of political power that fundamentally 'hollowed out' (Rhodes, 1994) the capacity of central governments to act and ultimately, it was thought, spelt the 'end of the nation-state' (Ohmae, 1996) propelling the region into the position of being the most significant spatial scale at which to make and deliver policy.

The recurring lesson to be taken from much of the work that serves to catalog and chronicle the ideas at the core of the new regionalism is that steadfastly holding to the neat administrative boundaries of local government often inherited from a period outside living memory, and obeying the rigidly defined responsibilities of what are in fact thematically overlapping public service providers results in disjointed and piecemeal planning policy. By extension, dealing with the inherently 'joined-up' nature of the problems with which regional planning engages necessitates cooperation and collaboration among the agencies that have individual responsibilities that might sensibly be aggregated. Stated alternatively:

> There are many different understandings of what regional planning comprises … because of its political roots, regional planning arises where established administrative and planning systems are overtaken by problems they cannot resolve … regional planning and governance can never be perfectly arranged, except in the moment. But since regional issues are recurrent, regional planning and governance are essential arts in continually managing a constantly imperfect system of government. (Wannop, 1995: p. 368)

From this point of view, regional planning is strategic in the sense that it serves to choreograph activities that cut across administrative geographies and institutional lines of accountability. In so doing, the intention is to provide a forward-looking, long-term framework that recognizes interlinkages between and across functional territories: for example, urban–rural interdependencies and transport planning related to extended commuting patterns. Ideally, planning at this strategic scale should, therefore, be better placed to objectively mediate where demand for resources and development pressures conflict with concerns over environmental conservation in a way that prevents local interests, such as opposition to new housing or infrastructure, overriding decision making in the wider public interest. Furthermore, in some contexts where an environmental feature, such as a mountain range, river, coastal waters, or lake, spans several administrative territories regional strategic planning can aid in supporting consistent management of such assets.

However, orchestrating this form of multiagency cooperation over what are by definition large territories has often proved difficult to achieve in practice. Indeed, regional planning's situation between the national (or federal) state and the geography of local government means that it systemically occupies the invidious position of being an intermediary, ideally providing a consistent translation of national policies downward and simultaneously representing regional and local interests upward to inform national policy debates. Research would suggest that this dual accountability coupled with the demands of coordinating the activities of multiple agencies across wide regional territories in a strategic fashion has been very demanding in practice – although by no means impossible (e.g., Glasson et al., 1997; Montgomery, 2011).

In sum, it seems clear that, with caveats about contextual specificities, the concept of regional planning either at a formal regional scale of government or through less formal partnership working across metropolitan regions came to be a relatively stable and enduring feature of planning practice across much of the Western world during the 1950s and 1960s and, in places, well beyond. For example, the previously referred to Clyde Valley Plan of 1946 remained in place until 1982. However, the continued conceptual relevance of regional planning in its original form subsided in light of the social and economic upheavals of the 1970s and 1980s. The stark differentiation between rapidly growing and shrinking urban settlements that characterized this period prompted a host of questions regarding the appropriateness of the metropolitan regional concept of regional planning dating from the 1920s to the1940s. At one extreme, population loss and urban shrinkage as a consequence of industrial collapse militated against the a priori assumption of a fixed or growing metropolis of sufficient scale to underpin a related regional form of politics or a genuine regional identity. In these areas, regional issues were now primarily related to urban regeneration, stimulating economic growth, repopulation, and, in some cases, managing decline. Conversely, exponential growth in other settings created suburban sprawl, the effective merging of neighboring cities into new ever larger regions and the emergence of significant functional economic geographies occupying a position beneath that of the state or nation-state and often representing new spatial configurations starkly at odds with existing political geographies: examples include Silicon Valley in California and Emilia Romagna in Italy.

The Region as a Space of Economic Development

This contrast in fortunes between economically buoyant regions with an acute exposure to the high growth sectors of the global economy (London and England's South East; New York and the tristate area) and those struggling to adjust to the postindustrial turn taken by the global economy pointed to the importance of the region as an economic space. From this starting point, policy makers' attention in the 1990s and 2000s turned to mapping the functional geographies of regional competitiveness in an attempt to catalog assets (airports, universities, and businesses) and identify synergies between them that might support a multiagential strategy for regional economic growth (Etzkowitz and Leydesdorff, 2000). In an academic sense, this understanding of the region as an economic container represents a continuation of a well-established trend among a community of academics working from the 1950s onward in the field of Regional Science. A melange of human geography, economics, and social statistics, regional science continues to be a thriving intellectual community using innovations in, for example, spatial econometrics to further our understanding of the global economy's disaggregation into subnational territories. Often,

the results of research in this field illustrate the anachronistic nature of administrative boundaries and demonstrate the complexities of functional economic geographies that often straddle local boundaries, state lines, and even national borders. Outside the academy, the impact of work of this type has been significant in influencing policy makers to focus attention on planning at a regional scale, even if this understanding of regions turns on an ostensibly apolitical conception of what a region might be in which functional and administrative space are not coterminous. Among the best examples of this stripe of academic work influencing policy can be found in the creation of regional development agencies in England at the end of the 1990s responsible for the development of regional economic strategies, the supervision of regionally significant infrastructure investment, and, more widely, representing their region in the global competition for resources (Deas and Ward, 1999; Webb and Collis, 2000).

Across Western Europe, similar steps were taken to institute regional development bodies (Haiker and Danson, 1997). In many cases, the creation of these institutions was cast as a statutory response to fundamental shifts in the global economy. On one level, the growing significance attached to regions by decision makers in transnational corporations regarding the location of their operations was said to necessitate a corresponding statutory presence at this scale to compete for internationally footloose capital – a form of regional planning bespoke to the neoliberal age of territorial competition. A separate economic logic, built upon the foundations of agglomeration and institutional economics, was also used to encourage a form of regional planning designed to harness the endogenous capacity of functional economic regions themselves (Porter, 1996).

From this perspective, regional planning in the 1990s and thereafter can be seen in a fundamentally different light to that which preceded it. The original concept, rooted in the postwar European ethos of municipal socialism, has usually been understood to have begun from the idea that taking a wider, strategic view was essential in creating plans with welfare objectives at their core. The results of this style of planning – large-scale public housing building programs in the 1950s and 1960s, for example – were often developed with social objectives to the fore and with only passing regard for what an untrammeled free market might have chosen to provide. By stark contrast, the regional planning of the 1990s and thereafter has focused largely on seeking to accommodate and coordinate the preferences of the free market. For example, rather than orchestrating state-led house-building programs, one of the principal responsibilities of the regional development agencies operating across Western Europe at this time has been principally to determine the location of residential development and infrastructure, in virtually all cases the bricks and mortar have been delivered by the private sector.

The Future: The Untimely Death of Regional Planning?

This implied shift in the suite of activities that might be undertaken in the name of regional planning has led to a fundamental reconsideration of the value of having such a tier of statutory planning in some contexts where right of center governments hold office. The palpable shifts in state–market–civil relations that have come to characterize the neoliberal age pose serious questions for an activity that in many settings has seen its role diminished from direct service provider to that of juggling the investment decisions and preferences of both private companies and individuals into a broadly coherent regional pattern of development. In some cases, these questions have manifested themselves as a backlash against both the very idea of 'regions' and the institutions once situated at that scale to provide a strategic planning function. Probably the best example of this at the time of writing is from Britain where the Conservative–Liberal Democrat coalition elected in 2010 made the reform of the English system of regional planning one of its first priorities. In the first instance, this impulse to reform was discursive with all references to 'regions' (or derivations thereof) expunged from official documentation and a promise that:

> Communities will no longer have to endure the previous government's failed Soviet tractor style top-down planning targets … I promised to get rid of them and today I'm revoking regional plans with immediate effect - hammering another nail in the coffin of unwanted and an unaccountable regional bureaucracy. They were a national disaster that robbed local people of their democratic voice, alienating them and entrenching opposition against new development.
>
> I want to make something very clear. Localism means much more than a tug of war of political power between Whitehall and the Town Halls. It's a fundamental shake up of the balance of power in this country. So power goes right back to the people who elected us. (Pickles, 2010)

The subsequent dismantling of England's regional state apparatus and its replacement with an uncoordinated bottom-up 'localism' focused on the smallest territorial scale (save the household), the 'neighborhood,' clearly points to a rejection of the idea that strategic planning at a higher territorial level is in some sense necessary to coordinate interventions across local authority boundaries (Baker and Wong, 2013). By contrast in other contexts, the region remains a fundamentally important tier of government, the strategic significance of which has become more rather than less important particularly in relation to confronting the most recently identified grand challenges of the twenty-first century. In this respect, adaptation to climate change, resource management, and planning for energy and food security are all features that are said to require the strategic scale of regional planning. Moreover, evidence would suggest that the earliest and most comprehensive plans designed to meet the local effects of these global challenges have come from contexts where some form of regional planning is an established part of the governing framework (e.g., Juhola and Westerhoff, 2011).

Given the enormous scale of the issues that our societies are likely to face as the twenty-first century continues, it is difficult to imagine how a comprehensive response could come through anything other than urban and environmental planning organized at a strategic scale. In small nations, this may be possible through centralization of some planning functions at the national level. However, in most cases, the region (widely construed) offers the most likely scale at which this form of strategic planning could be animated. In sum, for so long as

there are planning issues that cut across the administrative geography of local government and require a coordinated response regional planning is likely to remain a prominent feature of the planning polity across the globe.

Abstract

This article highlights the nature and purpose of regional planning and how the concept has evolved when applied in developing countries as regional development planning. It then turns to discuss the knowledge and skills required in the development of the doctrine of regional planning and their relevance to regional planning practice in the development contexts. Regional development planning and its evolution in China is then used as the case study to illustrate the complex relationships between technical rationality and political reality in delivery of different forms of regional planning.

The Introduction of Regional Planning

The concept of regional planning was first introduced by Patrick Geddes who began to develop his broader philosophy of regional planning in his 1915 seminal book, *Cities in Evolution: An introduction to Town Planning Movement and the Study of Civics*. He put forward a synoptic vision of 'place, work, and folk' to explain the symbiotic relationship between economic and sociocultural well-being. Through his planning work of the Edinburgh Zoological Garden, he illustrated the complex interactions between human systems and the natural environment, which led to his idea of developing regional planning models to respond to these complex conditions (Thompson, 2004). To him, the spatial contexts of past and present were critical to planning as city development should be seen as part of a wider spatial network of the city and the surrounding countryside.

Sparked by the ideas of Geddes, Lewis Mumford advanced a conception of regional development by taking an organic, ecological planning approach that aimed to balance the needs of the social world with those of the natural ecosystem. This regional approach to planning led to the establishment of the Regional Planning Association of America and the 'regional city' idea was advocated by Mumford, Clarence Stein, and other members in the 1920s (Meyers, 1998). The notion of a planned, polycentric city was then born, which emphasized on the importance of antisprawl and that individual settlements should be both distinct and interconnected at the regional scale (Talen, 2008).

The term 'regional planning' consists of the spatial entity of 'region' and the practice of 'planning.' The notion of a 'region' varies widely in different contexts and encompasses a whole variety of regions that may cover a third of China to a very tiny region in England. Harvey Perloff (1968) pointed out that regional planning had developed along pragmatic lines with relatively little attention to formal theory and defined it as

> the 'ordering' of activities and facilities in space at a scale greater than a single community and less than a nation, or, in the case of a common market situation where a number of nations are economically integrated, less than that of integrated totality.
>
> (Perloff, 1968: 153)

He also differentiated regional planning that were intended to strengthen national planning from regional planning that has specific objectives and operating components. He then settled on the fact that 'we must deal with a varied assortment of regions which are subsystems of a larger whole and change with the whole over time in both internal structure and external relations' (Perloff, 1968: 153).

Several decades later, Seltzer and Carbonell (2011: 9) view regional planning with similar flexibility: 'rather than encompass a territorial interest that is sharply bounded and represented (or at least claimed) by an institution that holds general governmental powers and responsibilities, it is carried out over a territory that, at least when that planning takes place, is found to share enough characteristics to assert its existence as a region.' Their definition emphasizes on how regional planning should be deployed to address cross-boundary issues across jurisdictions, which differs from the earlier concerns of the size and spatial extent of regions.

The designation of a region, in planning terms, can be based on its administrative or functional boundaries and is likely to include a network or a hierarchy of urban centers and urban and rural activities that have strong linkages and functional ties. The fluidity of the boundaries of a region asserts the crucial importance of interaction. The nature and intensity of interactions depend on what social–economic–physical activities are involved in the functional process (Hall et al., 1973; Parr, 2005; Wong et al., 2006). In this sense, the dynamic interaction between different activities over different spatial areas makes it difficult to delimit a region within a tightly bounded, single-minded physical framework.

Urbanization Challenges and Regional Development Planning

According to the UN Habitat (2012a), the amount of urban land will have to be expanded by 326% in developing countries to accommodate the projected growth of urban dwellers from 2 billion to 4 billion between 2000 and 2050. As highlighted by its Executive Director, Dr Joan Clos, 'Among the greatest challenges of the twenty-first century is the rapid growth of cities … Growing cities and towns face additional challenges, which include: high percentages of people living in slums; expansion and dominance of the informal sector; inadequate urban basic services, especially water, sanitation and energy; unplanned peri-urban expansion; social and political conflict over land resources; high levels of vulnerability to natural disasters; and poor mobility systems' (UN Habitat, 2012a: 3).

Regional planning in the global south context tends to focus on managing challenges brought by the rapid urbanization process

and reducing the chronic spatial inequalities between rural and urban areas. The UN Habitat (1997: ii) strongly promoted regional development planning as a framework for decentralizing the urbanization process and for the development of balanced national urban hierarchies. The most powerful change in the urban system has been continuing spatial decentralization. In the developing world, a defining feature of cities 'is an outward expansion far beyond formal administrative boundaries, largely propelled by the use of the automobile and land speculation… that urban land cover grew, on average, more than double the growth of the urban population' (UN Habitat, 2012b: 28). However, recent UN Habitat reports (2012a,b) have focused the discourse on urban planning and city management. This position has shifted somewhat from its 1997 report of adopting regional development planning as the strategy to manage the dynamic and continuous process of spatial change, to strengthen the linkages between secondary and intermediate cities, small towns and rural service centers, and to develop new growth centers.

The focus on urban development will easily distort the spatial dynamics operating between a city and its wider spatial context. It will depart from the strategic perspective of regional planning that 'was intended to reduce, and in the long run to eliminate, major inequalities of income among regions,' and 'striving for, are a growing awareness of the decisive role of natural resources in sustaining civilized life; a new ecological ethic; greater concern with questions of equity; a deeper understanding of the contradictions between the international division of labor and the territorial aspirations of new nation states; and a reassertion of the principle of self-reliance at all levels of territorial order' (Friedmann and Weaver, 1979: 2).

Planning in the development context tends to take place at the macro national level and the local level and pays little attention to the needs for coordination and mutual adjustment. Regional planning is, therefore, seen as a structure that can help to link the development potentials identified in local plans and initiative to national and sectoral planning (Van Staveren and van Dusseldorp, 1983: 1) by either disaggregating the national development plan and sectoral plans or aggregating local plans, programs, and projects into comprehensive regional development plans (Ahmad and Bajwa, 2005). With the mounting pressure of urbanization and the need to address short-term economic benefits of urban development and the longer term socioenvironmental costs, the concept of development has been broadened and planning has to be more comprehensive (UN Habitat, 2012b). According to Ahmad and Bajwa (2005), countries with centrally planned economies have gradually adopted regional territorial planning to complement their national sectoral planning, whereas countries relying on market mechanisms have also extend their 'master planning' from city proper to the wider urban scales of greater city areas, metropolitan region, and even megalopolis. Both these observed developments can be found in the case of China (to be discussed later in the article).

The Doctrine of Regional Planning

Since a region is very much seen as an open-ended subsystem, the planning of which has to accomplish the objectives of enhancing inter and intraregional development as well as managing spatial organization, the understanding of its wider spatial contexts such as the spatial flows and linkages of investment, people, goods, and other factors is critical to the development of a regional plan (Perloff, 1968; Rodwin, 1978). This means that effective development of regional planning has created a demand for certain types of professional skills and knowledge. As Friedmann and Weaver (1979: 6) commented, "The new doctrine of regional planning came to be supported by a new theory, appropriately labeled regional science. Interest in the philosophical foundations of regional planning had dissipated; marching with the times, planning had become a 'scientific endeavor'." The doctrine of regional science has focused on the problem of spatial organization in relation to urbanization, industrial location, intercity linkages, and redressing spatial imbalances via growth centers to induce growth and 'spread effects' from the growth center to the wider economy.

The assumption that ideas developed for regional planning can be applied in all sorts of regions has gradually changed, especially after gaining experience in less developed countries (Rodwin, 1978). The sophisticated knowledge and methodologies of regional planning have to be adapted to take into account the capacities and available data of different administrative contexts. Perloff (1968: 155) identified three key phases in the entire regional planning process for developing countries: the information analysis phase, the planning–programming phase, and the planning–operational phase. Based on the example of Latin America, he illustrated that each of these three phases of planning had its own requirements in terms of scope, content, and methods. Friedmann (1968) also set out 11 major steps in the formulation and implementation of different types of regional plans, programs, and budgets to achieve national objectives in developing countries. He then further identified 12 types of analyses (Friedmann, 1968: 133–134) to stipulate the technical requirements to be adapted for different regional planning conditions: analysis of spatial organization, locational analysis, urban complex analysis, regional land use analysis, analysis of demographic characteristics and behavior, human resource analysis, natural resource analysis, economic activity analysis, regional trade pattern analysis, regional accounts and development models, project analysis, and regional program budget analysis.

In spite of the progress and development in regional science and analytical techniques (Alden and Morgan, 1974), the findings are not always consistent. As Rodwin (1978: 122) commented, "the differences reflect different paradigms, values, and goals. That is why getting more and better data will not help very much." More importantly, the qualitative and quantitative measures of economic progress tended to show the unanticipated negative effects and the self-defeating effects of regional planning policies (Rodwin, 1978; Stohr and Todtling, 1978; Williamson, 1965). After reviewing the trends of regional planning practice, Rodwin (1978: 127) commented that

> A quarter of a century ago the problems of regional planning were deemed to be largely technical. Today they are not. In the main, the shift has occurred because pressing the political issues has become a way of challenging or even discrediting what is considered a wrong or inadequate technical approach just as raising the technical issue under some circumstances can become a way of skirting or discrediting a wrong or inadequate political process.

Ahmad and Bajwa (2005: 3) also echoed the importance of the political process:

> Like the input/output method, linear programming, or the critical path method in the economic sphere, regional analysis and regional planning cannot substitute themselves for the political process of decision-making.

In order to turn things around, institutional transformation had to be promoted in line with the pursuit of regional development and regional planning objectives. This argument remains true in many regional planning contexts.

Regional Planning in China

Since the Communist Party came to power in 1949, regional planning in China has been characterized by intermittent efforts to define and redefine its concept and scope to meet with different political and economic needs. The changing nature and emphasis of regional planning very much reflects the interaction between the development process and the wider socioeconomic circumstances at different time periods. China is, therefore, used as a case study to illustrate some of the issues identified with regional planning practice in the development context.

There is no official definition of what constitutes a region in China. The entire country is divided into different regions under the national 'five-year plan,' but the division varies over time. The most common classification in the prereform period was the six large cooperative regions (see Goodman, 1989: 188) and they were used for economic and social development purposes. Since the seventh five-year plan, the economic focus has been on three regional belts of east, middle, and west; nonetheless, these are not official regions. It is, therefore, difficult to pin down the spatial scale of 'regional planning' in the Chinese context as its usage and meaning have changed dramatically since the inception of the People's Republic of China. The current wave of regional plans tends to use 'region' loosely to cover all sorts of spatial configuration that are beyond the city plan to address issues that cross administrative boundaries. More importantly, different forms of regional plan are disguised under different labels such as territorial plans, urban system plans, urban cluster/ring plans, and metropolitan plans – they can all be categorized as hybrid 'regional plans.'

Regional Development and Planning: the Historic Context

Planning in China had long been synonymous with the soviet style of economic planning. A useful discussion of the changing physical planning system before and after the reform period has been succinctly provided by Wu (2007). Before 1978, physical planning was merely a subordinating mechanism (Nedovic-Budic, 2001) to allocate land use and infrastructural resources to achieve national economic and social development targets set out in the five-year plans (Leaf, 1998; Ng and Wu, 1995; Xu and Ng, 1998; Yeh and Wu, 1999; Tang, 2000). The preparation of five-year plans has been deeply engrained in the governing institution and has continued in the postreform period. The long-range goals outlined in the national five-year plans will then filter through to different levels of government to prepare their own five-year economic plans through the Development and Reform Commissions.

Besides the national economic planning framework, there are master plans for the built-up areas of cities. However, these statutory land use plans do not have complete coverage of the entire administrative area of cities. The word 'cities' (shi), as administrative units in China, carries a very different connotation from the western usage. Chinese cities have different administrative status, with municipalities at the top rank and under direct jurisdiction of central government (e.g., Shanghai and Beijing), through to provincial capitals and subprovincial cities, prefecture-level cities, and county-level cities. In municipalities, provincial, subprovincial, and prefecture-level cities, the urban area (*shiqu*) covers the urban city district, the adjacent subdistricts, and the suburbs, which is more akin to the metropolitan areas of the West. The only form of urban planning in China is city planning, which is a blueprint style, two-tier planning system with a master plan covering the urban city district and a detailed construction plan.

City planning before the economic reform was simply a technical land use plan prepared by the urban planning bureau to complement the five-year (economic) plan. Following the adoption of a more market-oriented economy in the post-economic reform period, the role of the state in direct resource allocation has changed and so has its city planning system. According to Wu (2007), city plans in China have undergone major changes in orientations in the postreform period. There has been a clear shift from the physical design-oriented approach to focus on the wider economic development objectives. With the accelerating rate of economic development, there has been increasing pressure over land use (Leaf and Hou, 2006). This prompts not only for a more effective control system to curb illegal development and urban sprawl (Yeh and Wu, 1999; Smart and Tang, 2005), but also for more strategic and analytical approaches in preparing city plans to promote urban development. The entrepreneurial ethos has inspired the production of a new form of concept (or strategy) plans to develop more strategic vision over infrastructural development and economic restructuring to increase the competitiveness of cities (Wu and Zhang, 2007). By examining the spatial relationship between places, these concept plans serve to bridge the missing spatial element in the five-year plans.

In spite of the production of strategic concept plans for cities, their restriction to the core built-up area does not provide a strategic spatial horizon to address the gravity of spatial challenges brought by global market forces. Since the Open Door Policy in 1978, foreign direct investment was initiated as part of the reform. Special economic zones were first created along the coastal areas and then along the Yangtze River. This has caused imbalanced growth between the economically buoyant regions along the east coast (particularly in the Pearl River Delta, the Yangtze River Delta and Bo Hai Gulf around Beijing and Tianjin) and those inland and lagging-behind areas in the middle and western regions. Such a differential growth rate has further reinforced the long-standing east–west poverty fault line caused by the differential local resources and historical trajectories of development in China (Edmonds, 1994). This leads not only to major migration flows from the less developed regions to the more economically successful areas, but also to the exploitation of natural resources from the less developed central and western

areas toward the coastal regions. This bears a significant impact on social equity, as well as ecological and environmental degradation problems at a national scale.

Rapid Urbanization and Planning Challenges

The recent relaxation over population registration control gives much greater freedom of rural–urban migration and the traditional administrative bifurcation of urban and rural becomes less important. Surplus rural workforce in less wealth-off locations can move to large cities to seek jobs. In spite of the wealth redistribution brought by the rural–urban migration process, what one witnesses in China is a widening gap between urban and rural locations. According to the National Bureau of Statistics (2005), over 26 million people living in rural areas were deemed as living in absolute poverty. This is a self-perpetuating process because the income gap encourages further rural–urban migration and, in particular, toward the metropolitan cities of Beijing, Shanghai, and Shenzhen. The urban–rural divide, in a strong economic sense, also translates into serious social tension and problems.

The consumption of land has been rapidly increasing following major industrialization and urbanization since the late 1980s. On the economic front, the government and major corporations have been actively adjusting land to construct industrial parks, key transport infrastructure, and public utilities. At the same time, rural–urban migration and the rapid growth of cities have led to rising demands of housing and commodity housing market booms (Tian and Wong, 2007). In order to cope with the development pressure, there has been major planned urban sprawl by local government. The expansion of urban and industrial use of land leads to a continued trend of rural and agriculture land reduction. This has caused stress on the carrying capacity of the environment and has created many unexpected ecological consequences.

These challenges prompt for a more strategic spatial approach for planning in China. President Hu Jiantao has issued clear directions (State Council, 2007) over the reconfiguration of spatial strategies to address key regional development issues of environmental protection, infrastructural provision, land use regulation and economic competitiveness. The concept of 'key functional regions' (*zhutigongnengqu guihua*) are adopted to serve as a framework for sustainable development by taking into account the spatial distribution of population, land use patterns, economic structure, and the urban/rural hierarchy. These new concepts and ideas from the upper level government have since been interpreted by local and provincial governments as 'directions.' Despite the lack of an official definition of regional planning, the government's emphasis on regional development and coordination means that economic regions are flexibly defined according to the characteristics and potentials of the economic, social, and ecological environment of each region.

Three Waves of Regional Planning

Chinese scholars (e.g., Cui et al., 2006; Wang, 2007) suggest that there have been three upsurges of regional planning over the last 60 years (see **Table 1**). Regional planning was first introduced as a successful soviet model in the early years of Mao's regime. The emphasis of development was on the prioritization of industrial growth under the centralized command economy. Regional plans were not merely tools to implement the economic goals of resource exploitation and population distribution, but to direct major industrial projects into the inland areas to realize the first and second 'five-year plans' (Wu, 2006). There was, however, a lack of effective intra-regional planning (Wang and Hague, 1993). Unfortunately, the implementation of these plans did not meet with the government's expectation of achieving economic revival. Following the fracture of the Sino-Soviet relationship in the early 1960s, this form of regional plans fell out of favor in the next 20 years during the turbulent political times.

It was not until the early 1980s, after Mao's regime, that there was a comeback of regional planning. The Open Door Policy has led to the contradictory strategy of adopting the free market mechanism while retaining the strong state control machinery (Lai and Lai, 1991). It also brought major uncertainties over interregional development balance with it as foreign investment was concentrated along the east coast. According to Wang and Hague (1993), it was these contradictory aspirations that motivated the government to adopt comprehensive territorial planning to address the competing imperatives. This new approach to regional planning drew on the experience from Chinese river control and land survey practices and land use planning systems in Japan and Western countries. It also adopted the Geddesian approach of 'survey before plan'.

Territorial planning was still very much grounded on the goal of gaining economic efficiency, particularly during the postreform

Table 1 Three Waves of Regional Planning in China since 1949

Wave 1: 1950s The Soviet model	Productivity distribution planning	Resource exploitation, productivity distribution, location decisions of large industrial projects, cities, and residential locations
Wave 2: 1980s–1990s Open Door Policy and orthodox regional planning paradigm	1980s: Territorial planning The Japanese and Western models	Exploitation, use, and protection of the territorial space – coordinate economic, environment, and population resources (later become land use plan that focuses on farmland preservation)
	1989: Urban system planning (first National Planning Act)	Spatial hierarchy and functional relationship between cities and region – designation of function, size, and allocation of each city and provision of infrastructure at the regional level
Wave 3: 2000 to now Globalization, urbanization, and sustainable development	Experimenting with new forms of regional plans and regional governance	Strategic spatial plans Conceptual plans At different spatial scales (from the whole state to counties) Cross administrative borders

entrepreneurial period, although it tried to strike a balance by maintaining a stable natural and human living environment (Wang and Hague, 1993: 565). This aimed to achieve the 'win–win' solution of sustainable development by having economic growth without damaging its environmental resources and resembled some of the underlying principles of the European Spatial Development Perspective (CEC, 1999) as territorial plans 'were conceived as a means of achieving horizontal integration of proposals from the vertical (multispatial scales) planning of enterprises and functional ministries within the command economy' (Wang and Hague, 1993: 566). Territorial planning also provided a vertical spatial planning framework. At the national level, it focused on identifying the location of key growth centers where human and natural resources could be sustained and at the provincial level, local planning commissions were encouraged to propose new development policies for their regions after the survey stage.

The experiment of the new form of territorial planning, however, ran into trouble as the lack of good-quality statistics and information for the mega regions seriously undermined the 'survey' stage of the plan-making process. As expected, practice tended to fall short of the ideal, the strong 'rational' principles that underpinned territorial planning did not fulfill its promise. More importantly, there was not an institutional structure to implement the strategies and the longer term time horizon did not work well with the pace of market economies. More importantly, even at its height, territorial planning was never a part of the statutory planning system. In 1991, following the reorganization of the central government departments, a new Territorial Ministry was set up to oversee territorial planning, which signified the demise of this strategic form of planning. The new ministry turned territorial planning into physical land use planning with a strong emphasis on farmland preservation, which greatly deviated from the original form of strategic regional planning.

Following the demise of territorial planning, the Urban Planning Department under the National Ministry of Construction set out a new form of urban system planning. This new style of planning was driven by the technical analysis of the relationships between cities and their region to develop a spatial hierarchy to optimize the functions, population size, and allocations of each city and to arrange infrastructural provision of the region. Such analysis was known as the 'three structures' (i.e., the rank-size structure, the functional division of labor structure, and the spatial distribution structure) and 'one network' (i.e., infrastructure network) approach (Gu, 1992; Song and Gu, 1988). This scientific yet simplified form of urban system planning had a big appeal to the government and has become part of the statutory planning system under China's first National Planning Act (1989). Since then, it continued to be the dominant form of regional planning and is implemented across different levels of government. Urban system planning tends to follow a normative paradigm of devising the perfect spatial form and it, therefore, fails to address the complexity of the regional system. More importantly, its bold assumption that regional development problems will be resolved through the three structures and one network approach does not always stand. It is thus criticized as rigid, pseudoscientific, and not implementable (Wang, 2007).

After the Asian financial crisis in 1997, a significant sum of foreign direct investment was redirected from elsewhere in Asia to China. The triple helix of market reforms, globalization, and the extraordinary rate of urbanization are seen as the driving forces that motivate key stakeholders to develop regional plans to express their visions of territorial development and to coordinate regional growth patterns. In spite of the significant efforts made to produce strategic urban plans, they failed to provide a strategic horizon to address the socioeconomic and environmental pressures brought by globalization. This has led to the third regional planning boom at the turn of the millennium. Unlike the city master plans, these regional plans tend to focus on deriving strategic guidance and governance structure to regulate and to coordinate, rather than dwelling on detailed spatial arrangements and the location of land use projects. Li and Wu (2012: 140) argue that 'the ups and downs of regional plans reflect the evolution of state power at the regional scale' and 'the rescaling of governance from the localities to the regional level.'

The Third Wave of Regional Planning

The different labels and names of the current wave of regional plans signify the diversity of their development goals. Examples of five broad types of plan that fall into the genre of regional planning are provided in **Table 2**.

'City-region plans' are a hybrid of traditional regional plans and master plans. These plans provide complete spatial coverage of the metropolitan area and apply the technical approach used in master planning. They focus not only on land use, but also on producing spatial strategies to coordinate development activities for the city-region. 'Cross-boundary regional plans,' however, aim to have some forms of collaborative mechanism in place to address pressing planning issues that transcend administrative boundaries. The move toward open markets means that local authorities are in direct competition with each other within the same region, although they share similar planning concerns. These plans help to improve the coordination of regional development to enhance economic competitiveness. There are also 'urban agglomeration plans' and 'metropolitan plans,' both of which are similar in nature and aim to develop strategies to coordinate the development of a network of cities. The urban agglomeration plan tends to cover a network of similar size cities, while the metropolitan plan tends to involve a major metropolis. Finally, 'urban–rural integration plans' focus on examining the functional complementary between urban and rural areas and to develop strategic frameworks to balance development in these areas.

In spite of the blossoming of different forms of regional plans, as far as the government is concerned, the only statutory regional plans are those called 'urban system plans,' although the nature and character of some of these plans have also changed dramatically in recent times to be more innovative and visionary rather than just about the normative hierarchy of the urban system. More interesting, the once waning territorial planning has been rejuvenated and has resumed its experimental role since 2000 (Niu, 2004).

Li and Wu (2012) distinguish regional plan making according to their top–down and bottom–up approaches. The former includes the Pearl River Delta Regional Plan (Xu and Yeh, 2010, 2011) and the Yangtze River Delta Regional

Table 2 Different types of regional plan

Plan types	*Examples*
Urban-region plans	Jiaxing urban-region master plan
	Ningbo urban-region master plan
Cross-boundary regional plans	Development plan for areas along Yangtze River in Jiangsu Province
	Urban belt plan along Yangtze river in Jiangsu Province
	Yangtze Delta regional plan
Urban agglomeration plans	Peal River Delta strategic plan
	Development strategic plan for urban Agglomeration around Hangzhou Bay area
	Mid-Shaanxi Province urban agglomeration construction plan
Metropolitan plans	Nanjing metropolitan area plan
	Suzhou-Wuxi-Changzhou metropolitan area plan
	Quanzhou half-hour commuting metropolitan area concept plan
Urban–rural integration plans	Nanhu district (Jiaxing city) urban–rural integration plan

Plan (Li and Wu, 2012) initiated by the central government to coordinate and regulate local and regional development, whereas the latter covers regional plans initiated by different layers of local government (Wong et al., 2008) to foster competitive advantage. After an extensive discussion on the emergence of centrally initiated Yangtze River Delta Regional Plan, Li and Wu (2012: 140) argue that regional plans serve as the 'spatialized' economic instrument for the central government to maintain some measures of regulation, both functionally and geographically, without inserting another tier of regional government. To them, regional planning is the result of the rescaling of state governance to manage political fragmentation caused by economic competitiveness of localities.

The analysis of various new regional plans in Jiangsu Province shows that these plans are largely driven by local interests to enhance their global competitiveness (Wong et al., 2008). Although they are not initiated centrally, they tend to be the product of an interactive top–down and bottom–up process involving different layers of government. There is a lot of rhetoric in the vision of these plans and the analysis is filled with fashionable spatial planning concepts and jargon, but with little substantive evidence to back up their usage. While environmental issues and rural areas are featured in the plans, they are predominantly urban based and economic oriented. These forces are shaping the planning process and governance structure as well as the content, rationale, and analytical principles of the plans.

The evidence so far suggests that regional planning in China has very limited actual impact other than promoting partnership working among different stakeholders (Li and Wu, 2012; Wong et al., 2008). Without the statutory status or a regional-tier governance structure to implement the regional plan, the coordination of economic, land use, infrastructure, environment, and other interests is undermined by the complex institutional structure and the jostling of power between different layers of government. It is thus difficult to argue that the latest surge of regional plans have so far achieved more balanced and sustainable development patterns. The casual usage of different terms and labels of the new wave of regional plans in China has obscured the understanding and obstructed meaningful debate over what a regional plan is (Wong et al., 2008). Of the various forms of regional plans, there are only two statutory plans – the urban system plan and the urban master plan. The irony is that there does not seem to be any regulation over the content and format of different types of statutory plans, which allows planning authorities to manipulate the labels and perform the 'new wine in the old bottle' trick. The lack of official status and a suitable institutional framework has resulted in a patchwork quilt of regional plans that are easily subject to the manipulation of local authorities to play one against another when they feel fit (Li and Wu, 2012).

These latest regional plans appear to be more strategic and comprehensive in nature when compared to the dominant form of urban master plans. However, the recent twist to the story is that the traditional urban planning framework was reformed by the enactment of the 2008 Urban and Rural Planning Act. Prior to this Act, the urban core (*zhuchenqu*) and suburban districts (*chengshi jiaoqu*) formed the 'planned urban area,' whereas counties beyond the suburban areas were defined as rural areas (Shieh, 2011). The 2008 Act, replacing the former Urban Planning Act, demarcated the watershed of including rural areas in the formal master planning system and that 'city-regions' become the spatial context for planning (Qian and Wong, 2012). Issues related to sustainable development such as arrangements of development land in urban and rural areas, environmental protection, and basic farmland protection are now required in this new form of master planning. However, the urban master plan can only provide general guidance for rural areas as the detailed planning of rural areas still falls under the township and village plan, which is separated from the mainstream urban plan. The new urban and rural planning system, therefore, cannot be argued as a bona fide integrative regional plan.

Conclusion

Friedmann and Weaver (1979: 6) postulated that 'the doctrine of regional planning will vary not only with national traditions in the practice of planning, but also with ideologies and underlying socioeconomic conditions.' The case of China has demonstrated the changing practice of regional planning to meet with different socioeconomic circumstances and political values and needs over time. While the techniques and methodologies of regional science are well developed, their

applications are highly constrained by the availability of robust data and evidence base. Technical rationality of planning alone cannot address the complex development challenges faced by local and regional actors. It is the political process and institutional changes that affect the ultimate delivery and practice of regional planning. China's two different types of regional planning demonstrate different rationalities. The planning over a larger region such as the Pearl River Delta or Yangtze River Delta is usually directed by the central government, aiming to enhance the coordination over different administrative units, while city-region planning for the core municipality is driven by local government to gain their competitive edges. However, both rationalities serve to provide an arena for different levels of governments to express their own visions and ideas to shape future development across the immediate built-up city areas. Many new concepts and ideas are thus introduced and debated, but more importantly, regional partnerships are emerging to develop new forms of local and regional governance. In order to manage the pressure of rapid urbanization and the socioenvironmental problems brought by globalization and climate change in developing countries, effective forms of regional planning have to continue to innovate the governance and institutional framework, decision-making process, content, and methodology of plan making to adapt to changing conditions.

Abstract

Regional planning may be defined as the integrated management of the economic, social, and physical resources of a spatially bounded area. Regional plans and policies have been proposed and carried out since the beginnings of civilized settlement. In the modern era, regional plans have been promulgated for sub-national, multi-jurisdictional areas such as metropolitan areas. Comprehensive regional plans have also been devised for poly-nucleated urban areas and for open regions such as river basins. Because, for historical reasons, regions often lack governmental organization congruent with their natural or economic characteristics, the realization of regional planning goals, policies, and projects has often been constrained or limited. Nevertheless, significant instances of the successful implementation of regional plans or elements of plans can be cited. Greater London, Paris, New York, and Chicago, for example, all have benefited from past efforts at regional planning. In an increasingly interdependent world faced with environmental degradation, economic development needs, and social inequities, there is a growing awareness of the need for effective regional planning in the form of integrated regional resource management. But pervasive fragmentation of political jurisdictions, dominance of short-term over long-term decision-making, growing inequities between economic classes, and the frequent absence of consensus on goals or future visions still present formidable obstacles to the realization of regional planning in both developed and developing nations. Powerful new tools for data management and monitoring, such as geographic information systems and computer-based visioning simulation, promise to be of considerable help in overcoming barriers to effective regional planning. However, these tools are no substitute for imaginative planning, political will, and a broad agreement on what future regions can and should become.

The Term 'Regional Planning'

'*Gallia est omnia in partes tres*.' All Gaul is divided into three parts. This command, from the reign of Julius Caesar in the first century BC, no doubt is one of the earliest example of regional planning. A region is a district or area defined by generally recognizable attributes, physical cultural, economic, or political. The word 'region' derives from the Latin '*regio*,' meaning direction or boundary, and from '*regere*,' to direct. Thus the concept of region embodies the interaction among place, people, and work or economy. A region may or may not be formally recognized as a political entity or sub-division. More likely a region is simply a shared mental construct of its constituents.

Regional planning then is the effort of the society or elements in the society to intervene in the integrated developmental evolution of the area in question. In ancient kingdoms, the wishes and wisdom of the ruler constituted the regional planning conception for the society. Values and objectives underlying regional planning and foresight particularly included protection from external threats, but also the provision of infrastructure – roads, water, the enhancement and protection of productive fields and forests, provision for population growth and economic development activities such as industry and trade, cultural enrichment, and provision for societal continuity in succeeding generations. These values and practices were often codified in religious beliefs and scripts. These values still underlie and are used to justify contemporary efforts to define and carry out regional planning.

At this point it will be helpful to discuss a few related words or concepts. We need first to distinguish regional from city planning. The concepts are related but city planning implies a *polis* or civic entity governed by elected or other recognized official bodies. A region does not necessarily have such official status. Indeed, often it does not.

Regional analysis is the study of the interaction of key variables – physical, social and economic – in a regional context. Regional science, a relatively recent evolution founded upon economic location theory, seeks to describe and predict systemic regional phenomena.

We need also to distinguish types of regions. The European Community is a region comprised of nation states seeking to develop a commonality of purpose and policy, which presumably will result in superior outcomes for its constituent members. The European Union thus practices a kind of multi-state regional planning, much as the federal government in the United States does for the aggregate of its 50 constituent states. Parts of nation-states also may constitute regions. One thinks of Scotland and Wales in the United Kingdom or the Appalachian Region or the Great Plains of the United States.

Another distinction among regions is between mono-nodal, multi-nodal, and non-nodal regions. Metropolitan regions are examples of mono- and sometimes multi-nodal regions. Natural resource regions are often non-nodal. River basin regions are another category: linear regions.

Regions can also be distinguished as growth regions or as lagging regions. Regions may lag in development behind national averages, due to lack of natural resources, limited accessibility, or cultural or educational factors. Much attention has been given to assisting lagging regions to 'catch up,' with mixed results.

Today, we hear much about 'integrated regional resource management.' and 'sustainable development.' These concepts, while imprecise and difficult to measure, are increasingly shaping the directions toward which regional policy planning is moving.

We should also distinguish between 'regional planning,' and 'regional plan.' A regional plan is a specific document which lays out in physical detail a future desired end-state. It may also contain social and economic policy statements. The regional plan is typically based on a regional survey of social, economic, and physical factors. 'Regional planning' is the process by which regional plans are made. 'Regional policy' is a related concept. Regional policies are, in effect, guidelines to realize or implement regional plans.

Origins and Practice of Regional Planning

The origins of modern regional planning doctrine can be traced to reactions to the oppressive conditions created by the Industrial Revolution in nineteenth century England and France. Robert Owen and Charles Fourier proposed utopian schemes for alternative workers' housing and communities. Piotr Kropotkin's *Fields, Factories and Workshops* (1901) offered insights into the connections of people, land and labor. Charles Booth's *Life and Labor in London* (1892) systematically surveyed the conditions of working class people. Ebenezer Howard's 1902 *Garden Cities of Tomorrow* presented an influential alternative to unplanned metropolitan expansion. Patrick Geddes, a Scottish biologist, published his *Cities in Evolution* in 1915. Geddes' synthesis of the salient connections among people, land, economic activity, and natural systems greatly influenced the American essayist and critic, Lewis Mumford. Mumford, in turn promoted Geddes' integrative approach to social and public policy through such books as *The Culture of Cities* (1938). Through Mumford, Geddes' ideas influenced the Regional Planning Association of America (RPAA), a progressive private group concerned with development which was active in the 1920s and 1930s.

The Regional Planning Association of America

The RPAA embraced Ebenezer Howard's idea to siphon off and channel new growth at the suburban edges of existing large cities into planned garden cities. The group also espoused the notion that economic growth should be decentralized to smaller cities and towns and diverted from large metropolitan areas. The RPAA was especially influential in New York State, where Governor Al Smith appointed Stein and his fellow RPAA colleague, Henry Wright, to a newly-created Commission on Housing and Regional Planning. In 1926, the Commission issued a regional plan for the state that called for a concentrated grid of lines of transportation and communication along major corridors, separation of cities and highways, and the creation of independent communities away from the centralizing tendencies of its major cities. Protection of forest, farmlands and recreation areas were also proposed. The plan had considerable influence on policy and some of its proposals were ultimately carried out. What is notable is that these policies and issues are still under serious debate some 75 years later (Spann, 1996).

The RPAA's conception of regional planning inevitably brought the group into conflict with the well-funded effort to create a Regional Plan for the New York metropolitan area begun in 1921 under the direction of Thomas Adams, a British town planner who had worked on plans for garden cities of Welwyn and Letchworth, and the Greater London region.

The Regional Plan of New York and Its Environs

The monumental Regional Plan of New York and Its Environs, begun in 1921 and published in 1929 (Committee on the Regional Plan of New York and Its Environs (1929)). The plan brought together many of the development trends and proposals of the time and was underwritten by generous grants from the Russell Sage Foundation totaling some $1.2 million. In 1990, this would be equivalent to roughly $20 million. The Regional Plan and Survey was and probably remains the best funded metropolitan regional plan ever undertaken (Hays, 1965).

The plan, encompassing 22 counties surrounding the Port of New York and targeted on the year 1965, incorporated proposals of the Port Authority rail plans, including those for belt line freight rail lines. Schemes for rapid-transit improvements, highway construction, zoning rationalization, and parks and parkways were assembled from a variety of sources and agencies and synthesized into a unified conception. The plan called for a 're-centralization' of industry and business, involving, among other proposals, a shift of manufacturing outward from Manhattan and the core of the region. Whatever its flaws, the 1929 Regional Plan of New York and Its Environs left a significant imprint on Metropolitan New York. The plan's basic physical planning conceptions were reflected in the subsequent development of the region.

The Regional Plan of 1929 clearly had a significant effect on the physical development of the region. But it also brought important changes in the institutional and public bodies concerned with regional development. Numerous planning and zoning agencies were established at the county and municipal levels as a direct result of field work by the staff of the Regional Plan. State policies for regional development were also stimulated by the plan and its advocates. The plan also influenced the Depression-era New Deal policies of the Roosevelt Administration. President Roosevelt was well-aware of the ideas of both the RPAA and the Regional Plan of New York.

Roosevelt spoke at a Roundtable on Regionalism held at the University of Virginia on 11 July 1931 on the need for regional planning and development, aided by the initiatives of the federal government to lead the country out of the economic stagnation it had found itself. Thus Roosevelt was instrumental in getting the thought of Southern Regionalists, such as Howard Odum and Rupert Vance of the University of North Carolina, and the ideas of the RPAA group onto the agenda of the New Deal. This may have been the origin of the idea for a Tennessee Valley Authority (TVA) in Roosevelt's thinking. On a national scale, the New Deal also created a National Resources Committee to survey the needs and resources of the country.

The Tennessee Valley Authority

The Tennessee Valley Authority (TVA) was the first of the river basin or other large regional agencies to attempt to bring together the then-new concepts of integrated resource development, which was central to the conservation ideas of the

time, and regional planning which was a part of the new city and area planning movement.

Roosevelt's early speeches and papers clearly reveal a deep-seated and long-standing concern with farm problems, rural poverty, and the inadequate methods of providing services to rural areas. He also saw these problems as coupled with those of overcrowding and poor living conditions for the working people in the big cities, which he believed were fueled in part by the migration from farms to cities. The emerging concepts of regional planning seemed to Roosevelt to provide the linkage between the two problems. It is within this context that the regional planning ideas of Roosevelt were appended to earlier ideas for a multi-purpose plan for the Tennessee River, which had focused on flood control, navigation, and power generation. The main body of the TVA Act, as introduced on 9 March 1933, consisted of a comprehensive river improvement program plus two sections which provided for surveys of regional development problems and for recommendations to Congress on necessary legislation to solve these problems. The river improvement sections of the TVA Act were very explicit and provided for a navigation channel from Knoxville to the Ohio River, flood control to protect valley cities and to help control floods on the Mississippi River, and power generation. In contrast, the regional planning sections were very general and thus susceptible to either broad or narrow interpretation. TVA's mandate to conduct and implement regional planning was never clear or unambiguous.

The National Resources Committee (later the National Resources Planning Board) envisioned TVA as the first of a nationwide array of river basin planning regions. TVA was viewed as a model for the rest and as a testing ground for new communities as originally proposed by the RPAA group. The first of these was Norris, Tennessee, built near the first hydroelectric dam, Norris Dam, originally to house construction workers, and then to be converted to housing for the local populations dislocated by the rising waters of Norris Lake. Roosevelt's grand vision for river basin regional planning initiatives was thwarted by the interventionist scale of the vision, in a country dominated by unregulated market forces, and by the outbreak of World War Two. TVA nevertheless became a model for numerous grand multi-purpose hydroelectric and irrigation projects around the world, some misconceived and contrary to sound, integrated regional resource planning and management principles. Sadly, TVA itself has relinquished any serious commitment to regional planning leadership and has become, in effect, primarily a publicly-owned wholesale electricity producer.

Appalachian Regional Commission

Besides TVA, America's other important multi-state regional planning effort has been the Appalachian Regional Commission (ARC). Like TVA, the ARC was created to deal with an economically lagging region, the mountainous, relatively inaccessible chain of counties stretching from Alabama and Georgia to the Southern Tier of Upstate New York. The ARC began as an idea of President John Kennedy, who toured West Virginia's poverty-stricken mining towns in his campaign for the White House. The ARC was established in 1965 in the Johnson Administration. The ARC developed a plan for improving access and social services for isolated communities in parts of 13 states. Highway improvement and infrastructure programs were central elements of ARC regional development. Thirty years later, assessments of the effectiveness of federal investments in the region are mixed. But according to one comprehensive study, the federal investment infusion seems to have been effective. Counties in the ARC program were noted on average to have developed faster economically than comparable counties not in the program (Bradshaw, 1992; Isserman and Rephann, 1995). ARC was still functioning in the year 2000 but other federal regional development efforts such as the eight Department of Commerce Title V regional commissions setup in other lagging regions of the US were not so fortunate. All were closed down in 1980.

Metropolitan Regional Planning

The post-war era in the United States, with its spreading suburbs and growing automobile dependency, raised new issues for regional planners, notably in the large metropolitan areas. Federal aid for metropolitan planning became available with the enactment of Section 701 of the Housing Act of 1954, stimulating the creation of planning commissions for the nation's metropolitan areas. By 1960, two-thirds of US metropolitan areas had some form of area-wide planning and, by 1971, thanks to federal grants and statutory requirements, all of the nation's 247 metropolitan areas had adopted official regional planning, mostly through elected, voluntary, Councils of Government (COGs). The A-95 review process, which required regional review and coordination to receive funding for large scale, federally-assisted projects, and Section 208 of the federal Clean Water Act of 1972 further stimulated the creation of regional planning bodies in metropolitan areas.

In the New York Metropolitan Region, the privately-supported Regional Plan Association produced a Second Regional Plan for the New York metropolitan area, released in November 1968. The Second Regional Plan emphasized the creation of regional sub-centers linked by fast rail to Manhattan to expand job opportunities for those trapped in the central cities. For the suburbs, these centers would provide an organizing focus for social and civic life, employment opportunities, and easy access to and from Manhattan. The centers would be composed of 'regional activities' which would have to be built in any event to accommodate the expected additional 12 million people who would join the 18 million already in the 31-county region (expanded from the original 22-county definition) by the year 2000.

Forecasts for a large shift in employment away from manufacturing to service and white-collar jobs suggested the potential for significant office growth, some of which could go to centers outside of Manhattan. The plan proposed massive new office development for Manhattan, both in downtown and midtown but the plan also proposed that regional centers be built, both as redeveloped inner-city sub-centers such as Downtown Brooklyn, Jamaica and Newark, as older city centers in suburban cities, or as entirely new centers on open land. The centers idea took hold in a number of places, notably Jamaica, Queens, Downtown Brooklyn, and Fordham Road in the Bronx. Downtown Newark also experienced new central place

development and expanded centers were developed in the outlying areas of White Plains, Stamford, and New Brunswick.

The Second Regional Plan draft addressed other issues as well. Its housing policies called for increased densities, a more compact region, better related to accessibility to jobs and activities, and more housing opportunities for lower-income and minority families. The draft also called attention to the continuing need to capture more open space and to deal with the increasingly difficult problem of waste management. The plan called for completion of the region's share of the interstate highway network but it also made a strong case for the preservation and enlargement of existing rail transit systems.

In the 1980s, regional planning in the United States suffered a severe setback when the federal government withdrew virtually all its support for regional planning agencies, resulting in the demise of many programs. Only the transportation planning function survived in most metropolitan areas. TVA and the Appalachian programs managed to continue, though their planning functions were greatly reduced. Some states replaced federal assistance for regional planning with state funds. Other regional agencies survived by becoming more entrepreneurial, focusing on service delivery. A few states such as Florida, Georgia and Massachusetts, concerned about the negative aspects of growth, have developed growth management or 'Smart Growth' initiatives, which require regional planning as a framework for development policies, in some cases.

Regional cooperation in politically fragmented metropolitan areas has generally proved difficult to realize in the United States. A number of metro areas, however, have managed to achieve success in facilitating regional planning consensus. The Twin Cities region of Minneapolis/St. Paul, and the Portland Oregon region are often cited as examples of successful regional initiatives. The Minnesota Twin Cities area created in 1967 through state legislation a seven-county Metropolitan Council. The Council was created to address specific region-wide problems such as sewers and transportation. The Council has adopted a development guide for regional and local decision-making that identifies planned urban areas and growth centers. The Twin Cities regional initiative has enjoyed some major success, though its planning function has been scaled back in recent years.

The Portland Oregon three-county region in 1979 authorized by referendum a metropolitan service district. The district provides technical assistance and reviews local plans. In 1992, the Metro, as it is called, was given approval by charter to adopt a regional framework plan to guide regional development. The framework plan will address land use, development densities, housing, transportation, natural areas, and water supply. The Portland process is generally viewed as a successful example of the application of effective regional planning to control the negative aspects of rapid growth, though some concern has been raised about the impact of controls on the housing costs.

Metropolitan regional planning has experienced a resurgence in the 1990s in a number of American urban areas such as San Diego, California and Chattanooga, Tennessee, while, in the New York metropolitan region, the Regional Plan Association released in 1995, a Third Regional Plan, successor to the 1929 Regional Plan of New York and Its Environs, and to its Second Regional Plan of 1968 (Yaro and Hiss, 1996). The Third Plan has focused on ways to help the region recover its momentum so as to maintain its faltering position in the global marketplace. To address the problems facing the region, the Third Regional Plan proposes five ambitious campaigns focused on open and green space, transportation improvements, strengthening urban centers, improving workforce skills, and streamlining governance structures. It remains to be seen whether the Third Regional Plan will have as much impact as its two predecessors.

British and European Regional Planning

The trajectory of regional planning in Britain and Europe has somewhat paralleled that of the United States. Regional planning in post-World War II Britain found new support and momentum. The New Towns idea was re-embraced as a means to rebuild a Britain exhausted by war. Regional plans for the utilization of the old, lagging industrial regions of the North of England, Wales, and Scotland were adopted. These provided for decanting of populations into a new generation of expanded and new towns. Older urban areas would be contained within protected greenbelts.

In the 1960s, regional planning was further spurred by commission reports concerned about fast growing areas, notably in the Southeast of England. Metropolitan regional planning, mainly advisory, was undertaken by county and regional councils. Their mandate was to:

1. work out broad objectives for each region and provide a framework for detailed sectoral decision-making;
2. advise on national policy-making where it could significant affect regions;
3. advise on the application of national policy in their region; and
4. help create a consensus within a region as to its problems and possible solutions.

Regional planning tended to be more favored by the Labor Party, less so by the Conservatives. The Conservatives tended to view taxation for social schemes and infrastructure as a burden on business and regulation and control of development as disincentives to market responses to problems of growth. The Thatcher government in the 1980s reconfigured regional planning bodies and responsibilities: the Greater London Council and other regional councils were abolished and regional planning was transformed into a mechanism for assisting large-scale private redevelopment schemes.

With the return of a more liberal-left government in the 1990s, there has been a modest return to regional planning initiatives. These initiatives, however, have continued the private/public partnership approach promoted by the Thatcher government. The central government places more emphasis on local government bodies. Grand regional planning schemes are not in vogue, as pragmatism and incremental and market approaches are more the order of the day. Whether this approach will enable the UK to meet the challenges of the first decades of the new century remains to be seen. With continuing population growth, a deteriorating environment, limited local resources, and continued un- and under-employment in some regions, together with a need for further integration into the European system, Britain faces hard choices. Robust, effective regional planning and implementation intermediate between

the central government and local governments would appear to be a prerequisite for meeting these challenges. Whether the political climate will permit and support an articulated interventionist approach remains to be seen.

On the European continent, regional planning has been practiced with considerable success in both France and the Netherlands. France, with its strong provincial history and identities, has been able to focus its regional planning efforts on channeling excessive growth away from the Paris region toward second- and third-order city-regions. Meanwhile, the Paris region has benefited from metropolitan region planning and development that has focused on transit-based development and suburban centers. Regional planning in the Netherlands has emphasized a '*Randstadt*' plan which focuses development on the ring of cities surrounding a protected green center in the middle of the country. The European Union has fostered regional cooperation among regions that share common characteristics. An example is the Atlantic Arc Region, the grouping of the regions of EU member country fronting the Atlantic Ocean, which share technologies and cooperative approaches to managing planning and development.

Future Prospects for Regional Planning

To summarize, it is reasonable to say that regional planning in western industrialized countries has historically had a checkered history of meeting the challenges of growth and decay at the sub-national level. But it is also accurate to point out that those areas that adopted and tried to carry out regional planning schemes have often achieved better results than those which simply drifted into incremental, piecemeal development. It is almost always an advantage to have some systematic framework and political consensus on which to build, even if all relevant variables cannot be predicted or controlled.

There is reason to believe that regional planning will enjoy new vitality and acceptance. Powerful new forces, needs, and demands are compelling a renewed look at the desirability of regional planning approaches. Globalization trends are fostering the integration of economies on an international basis. Metropolitan economies are increasing seen as the building blocks of a world trading system. The communication and air travel revolutions have reduced the accessibility advantages enjoyed by a few large cities. Competitiveness will require regions to make the most of their assets, and grow new ones. This will take conscious, deliberate, smart planning. Environmental pressures and the deterioration of air, water, and land have reached serious proportions in many countries. Regional approaches will be needed to address the pollution of air and water sheds, which rarely conform to the boundaries of local jurisdictions. Global warming and the need to reduce carbon emissions will inevitably require regional approaches to the transportation and land–use interface. Sustainability is becoming the norm by which regional development decisions increasingly are being judged. More attention is being paid to the protection of natural and cultural amenities, natural habitat, green areas, wetlands and waterways, which, by their scale, mandate regional approaches. At the same time, the digital revolution has provided policy-makers and the public with new tools to collect, manage, and display vast amounts of relevant data, in ways only dreamed of in the early years of regional planning. Powerful computer-based geographic information systems (GIS) now permit mapping and analysis of trends, projection of impacts, and improved understanding of alternatives by regional bodies. This new capacity will surely enhance regional planning possibilities and effectiveness in many areas and countries.

Abstract

This historical assessment of the history of regional science includes a description of its membership as regionally disaggregated association sections were consolidated into a global organization of some 4000 members. The theory, methods, and practices of the field are highlighted along with names of major awards contributors have received.

The origins of regional science are traced from the 1920s, stressing its interdisciplinary nature. The subject matter of regional science is then considered, focusing on location theory, methods of regional and spatial analysis, and regional development and policy. Next, the intellectual progress of the discipline is charted, looking in particular at location and spatial patterns, methods of regional analysis, and the explanation of differences in regional development.

Economists pay too little attention to the location of economic activity and the effects of distance on economic systems. Geographers focus on the spatial dimension but lack rigorous tools to study the effects of location and distance on human behavior or explain why activities are located where they are. Urban and regional planners need a stronger analytical foundation to go beyond the physical and aesthetic aspects of urban form to consider social and economic dimensions of city and region. With such premises, 60 economists, geographers, political scientists, sociologists, and planners gathered at the annual meeting of the Allied Social Science Associations in 1954 and founded the Regional Science Association. Its objective was 'to promote studies focusing on the region.' Envisioned were the use of theoretical frameworks and methods of the social and other sciences and the development of new ones specifically for regional analysis.

This interest in the region as a subject of study had important and immediate political and intellectual antecedents in the United States. In 1927, the regional plan for New York considered economic factors in metropolitan growth and spatial form, largely through the work of Robert Haig. In 1933, the Tennessee Valley Authority became the nation's first major regional development program, arguably since the Western expansion. In 1935, asserting that policies of national development depend on regional factors, the US National Resources Committee asked 'modern students of regional science' (10 regional geographers and 2 regional sociologists) to identify the best type of region to use for regional planning and development. In 1942, Alvin Hansen, perhaps the leading American Keynesian economist and a Harvard professor, advocated a comprehensive postwar expansionary program of regional development on the premise that the effective utilization of resources in any region makes the whole nation richer.

Two organized, interdisciplinary efforts with very different intellectual roots had focused on regions. In the 1920s, Lewis Mumford and his colleagues in the Regional Planning Association of America saw cities as congested and unmanageable. They advocated a mode of thinking and procedural methods aimed at seeing the region as a whole – integrating city and region, and utilizing, not destroying, the natural environment. Closer to the regional scientists because of their emphasis on both science and the region and their scholarly university base were the southern regionalists. Centered at the University of North Carolina, they were well established by 1931 in terms of research achievements, agendas, and infrastructure. Howard Odum, the acknowledged leader of the effort and a sociologist, argued in 1945 that the nation owes the fullest development of the South not only to the South but also to the nation itself. Similar in ambition but predating the Regional Science Association by a quarter century, Odum advocated a regional approach to the scientific study of human society, arguing that it would entail the integration of method and theory, require the joint effort of the traditional social science disciplines, and create fundamental new understanding of all society, not just its regions.

Members of the Regional Science Association from the outset debated whether regional science would become a new discipline or an interdisciplinary field.

Walter Isard, widely recognized as the father of regional science, was the leading proponent of the disciplinary view. In 1956, he became an economics professor at the University of Pennsylvania, where he formed the Department of Regional Science in 1958. By then he had published 23 papers in the leading economics journals (acknowledging the help of Alvin Hansen in the first five). Yet the Regional Science Program would go far beyond economics in its scope and impact. In 1960, the first PhD in Regional Science was awarded to William Alonso, later regional planning professor at Berkeley and Saltonstall, Professor of Population Studies at Harvard. Subsequent doctoral recipients took positions in economics, engineering, geography, planning, and other university faculties as well as public agencies and consulting firms.

Isard's prediction that regional science programs would emerge from geography departments and achieve wide recognition before 2000 was not realized. In the 1970s, Cornell University established the second Regional Science PhD program, and the University of Illinois initiated a multidepartmental program requiring completion of the PhD in a participating department. By 1976, regional science degree programs or specializations existed at 14 universities internationally. The lone department devoted exclusively to regional

[†] Deceased.

science remained the one at Pennsylvania until it was closed during university retrenchment in 1994.

Among the early challengers of the disciplinary view was Lloyd Rodwin, a planning professor at the Massachusetts Institute of Technology. He envisioned the social sciences developing more systematic spatial studies, geography becoming more analytical, and regional science becoming 'a generic name for regional studies.' This vision has become reality, but not fully. Regional science has become a generic name for a certain kind of regional studies, one whose origin is in mathematical abstraction and quantitative modeling.

Today regional science is an international, interdisciplinary endeavor. It brings together economists, geographers, planners, and others whose research has a regional dimension. It is the confluence of many streams, but arguably also the origin of a few. Each discipline brings different theoretical and methodological approaches to regional science, and each typically has different substantive concerns within a given topic. Migration, for example, interests several disciplines. An economist might focus on migration behavior as a way of measuring quality of life in cities, a demographer on regularities in the age pattern of migration, a geographer on turnarounds in core–periphery migration, a planner in forecasting migration for land use and transportation modeling, a sociologist on the effect of kinship links on migration destinations, and a real estate specialist on the relationship between housing prices and migration.

The numerous scholarly regional science journals and annual conferences create effective forums for exchanging ideas among disciplines. Although dominated by the abstraction and modeling inherited from economics, these forums are eclectic and open. They have been helpful incubators for scholarly groups who went on to create their own forums, be they input–output analysts, spatial social theorists, urban economists, or transportation modelers. Collectively regional scientists actively borrow ideas from a wide range of sources and combine, adapt, and extend them to regional research.

The recognition Isard anticipated has materialized in many ways other than through a proliferation of university departments. The Regional Science Association became the Regional Science Association International (RSAI), an umbrella organization overseeing three major supraregional organizations, the North American (today the Americas), European, and Pacific coordinating councils. Most countries in Asia, Europe, and North and South America have active regional science associations, and there are several multinational ones, including the British–Irish, French-language, German-speaking, and Australia–New Zealand organizations. New associations have been established in South America including Argentina, Chile, Columbia, and Brazil. The Mexican Association has existed since the 1990s. Many of the individual organizations like, for example, the Western Regional Science Association have a diverse following of foreign members who often rise to leadership positions. Most of the associations sponsor annual meetings, and several have journals. A list of regional science associations may be found at www.reigonalscience.org.

A widely accepted notion is that almost all regional scientists have dual identities, economist and regional scientist, geographer and regional scientist, and so on. For many, the regional science meetings and journals provide the best audience for honing and distributing their research. Others' participation ebbs and flows with changes in their immediate research agendas. No complete census of this fluid regional science community exists. The associations together, including those in China, India, and Brazil, may have over 10 000 members combined. RSAI itself has about 4000 dues-paying members annually.

Regional science journals have become numerous and well established. Six international ones with regional science in their titles are now published by major commercial presses: *Annals of Regional Science*, *International Regional Science Review*, *Journal of Regional Science*, *Papers in Regional Science*, *Regional Science and Urban Economics*, and *Regional Science Policy and Practice*. Echoing the debate half a century ago about the name 'regional science,' some regional science associations leave it out of their journal titles, for example, *Journal of Regional Analysis and Policy Review*, *Urban and Regional Development Studies*, *Growth and Change*, *Investigaciones Regionales*, *Review of Regional Studies*, and *Applied Spatial Analysis*. The RSAI lists 32 related journals worldwide (see www.regionalscience.org).

Book series, position announcements, honorary degrees, and external research prizes are other marks of regional science's role within the social sciences. Noteworthy, too, are the National Science Foundation's Program in Geography and Regional Science in the US and similar ones in other countries. Perhaps the most spectacular recognition of regional science occurred when the Emperor and Empress of Japan personally welcomed participants to the RSAI World Congress in 1996.

Subject Matter

The international regional science community studies a wide range of topics, sometimes ambitiously defined as those social, economic, political, and behavioral phenomena that have a spatial dimension. A common, narrower view groups regional science research under three themes: location theory, methods of regional and spatial analysis, and regional economic development and policy.

Location theory is the study of what social and economic activities are located where and why. Traditionally, emphasis has been on the location of firms and households. The latter considers interregional and international migration and labor markets, as well as intrametropolitan residential mobility and housing markets. Early contributions focused on the role of transportation costs and proximity to suppliers and markets. Recognizing interdependencies of behavior focuses attention on agglomerations or clusters in space, as well as on questions of land use, urban form, housing markets, city size, hierarchies among and systems of cities, market thresholds, and market boundaries. Recognizing interactions among activities and individuals distributed over space raises questions about commuting, trade flows, congestion, transportation, other infrastructure, facility location, taxes, user fees, local public finance, and diffusion of innovations and growth.

The phrase, methods of regional analysis, describes a growing set of techniques used to identify, analyze, or forecast key regional characteristics or changes and to test

theoretical hypotheses. Among the methods are three invented to study national economies but adapted to regions. The inventors received Nobel Prizes in Economic Sciences: Wassily Leontief (1973) "for the development of the input–output method and for its application to important economic problems," Lawrence Klein (1980) "for the creation of econometric models and their application to the analysis of economic fluctuations and economic policies," and Sir Richard Stone (1984) "for having made fundamental contributions to the development of systems of national accounts." Regional scientists have adapted and extended techniques from demography. The cohort-component model focuses on the components of population change and their probabilities (births, deaths, and migration), grouping the population into cohorts by age, sex, and often race or ethnicity. Regional scientists borrowed and adapted the gravity and entropy models from physics and found that they described certain aggregate human behavior well. Migration, trade, transportation flows, and other interaction between two places tend to increase with the product of their masses (e.g., populations) and decrease with distance between them. Regional scientists have also adapted and applied optimization techniques (e.g., linear programming and its many variants) to contexts in which spatial interaction is important, such as transportation networks, location of facilities, and land use.

Regional scientists use statistical methods extensively. Yet here, too, important adaptations and extensions permit the study of spatial and regional phenomena. Geographers, in particular, have extended standard statistical concepts to situations where observations have locations, for example, to draw random samples over space or to determine the likelihood that an observed locational pattern could have occurred by chance. Spatial statistics, spatial econometrics, geographical information systems, and other methods of spatial statistical analysis have become major parts of regional science – for economists, planners, engineers, and others as well as geographers. In the case of statistical methods widely used to study travel demand, residential location, migration, and other behavior with a spatial dimension, the pioneer was an economist, Daniel McFadden, who won the Nobel Prize in 2000 "for his development of theory and methods for analyzing and modeling discrete choice processes."

Regional economic development and policy focuses on why some regions grow and prosper while others lag and even decline, as well as other things such as innovative cluster dynamics, agglomeration impacts, and entrepreneurship as factors or drivers of development and growth. Research ranges from theories of growth and development to the evaluation of specific policies. Persistent questions deal with the divergence and convergence of regional growth rates and incomes, the relationships between core regions and peripheral regions, and the geography and timing of the spread of growth. Other long-standing questions deal with regional labor markets, including the relationship between growth and unemployment and the persistence of wage differences among regions. Key policy issues concern people prosperity vs place prosperity (should the focus be on helping people directly, for example, through education or out-migration incentives or on helping people indirectly by making the region more competitive through infrastructure, tax incentives, or other actions), ways of making lagging regions more competitive and prosperous or more robust regional economies more stable, the rationales for regional policy, and the roles of different levels of government in policy making and implementation.

Policy evaluation has attracted much attention as well. Commonly the objective is to measure the effects of various (nonregional) national policies on regions, for example, free trade treaties, defense spending, or tax reductions. In other cases the objective is to evaluate regional policies, for example, by estimating what would have happened to lagging regions in the absence of the regional support programs. And sometimes the emphasis is on comparing alternative regional plans or policy instruments before they are implemented, generally using cost–benefit, cost-effectiveness, or goals achievement methods augmented to include policy objectives, distributional issues, and hard to quantify outcomes.

Intellectual Progress

Two easily contested, unavoidable decisions must be made before discussing the intellectual progress of regional science. The first is whose contributions should be counted. The open, fluid nature of the regional science community makes this decision difficult, and the early claims to disciplinary status make it controversial. The perspective here is that the idea itself is more important than the primary tribal self-affiliation of its originator. The key criterion is whether the idea is part of the scholarly conversation in regional science meetings and journals. Mention of an individual's contribution does not imply that the person considers himself or herself a regional scientist, although each person mentioned has participated in regional science meetings or published in regional science journals. Debates about whether particular intellectual contributions were initiated by regional scientists, borrowed by regional scientists, or adapted by regional scientists, and who is really a regional scientist are fruitless. The gravity model provides an early case in point. One observer described it as work that may clearly be termed regional science, while another argued that it had been pioneered by outsiders and applied in many disciplines. By far the most interesting fact here is how understanding and use of an idea have evolved.

The second decision concerns the scope of regional science. Something narrower than human activities and phenomena with an important spatial dimension must bound this discussion, but may offer too incomplete a view. Some describe regional science as a toolbox for practical analysis that lacks rigorous theory, while others decry it as a theoretical never-never land with too little realism. The path chosen here recognizes Isard's deliberate efforts to nurture the field of regional science. He edited several of its journals, commissioned papers, supported dissertations, organized meetings, and shaped an influential book series. Three of those books frame a useful way of discussing regional science: Isard's *Location and Space-Economy* (1956), the Isard-led collaborative effort, *Methods of Regional Analysis* (1960), and a reader edited by John Friedmann and William Alonso and dedicated to Isard, *Regional Planning and Development* (1964). The books'

foci – theory, method, and policy – frame the discussion of intellectual progress well.

Location and the Spatial Economy

The quest here is to model mathematically and show graphically both the determinants and consequences of individual location decisions. Regularities in spatial patterns are readily observable, among them are the emergence and persistence of large cities, hierarchical networks of urban places as envisioned in central place theory, clusters of related industries, relatively homogenous residential areas within cities, and regularities in city size distributions. The goal, chiefly of economists who work in this tradition, is to show how these agglomerations can materialize from the interaction of self-serving decisions of individuals and firms. Isard's book drew on the pioneering German contributions by Johann Heinrich von Thünen, Alfred Weber, August Lösch, and Walter Christaller.

Two works from the birth period of modern regional science were extraordinarily seminal. Alonso's dissertation, *Location and Land Use*, focuses on transportation costs and its role in residential decisions and the resultant land-use patterns within a metropolitan area. Concentric rings of land use emerge from the behavior of utility maximizing individuals. Alonso's starting point, like von Thünen's, is the existence of an agglomeration, in this case the central business district of a monocentric city. Charles Tiebout, a founding member of the Regional Science Association, argued that 'people vote with their feet' by choosing locations within the metropolitan area that offer the combination of revenue and expenditure patterns that appeal most to them. Thus, spatial mobility among diverse communities within an urban area provides a solution to the collective consumption problem posed by Samuelson and another mechanism by which individual preferences create spatial variation. Much of today's field of urban economics builds on these two contributions.

A contemporary contribution of this genre is *The Spatial Economy* (1999) by Masahisa Fujita, Paul Krugman, and Anthony Venables, which they describe as a continuation and possible validation of Isard's project. It derives agglomerations instead of positing them as a starting point (e.g., Alonso's central business district around which commuters organize themselves). In the 'new economic geography,' as Krugman (received the Nobel Prize in economics in 2008 for related work) calls it, agglomerations result from the tension between centripetal forces that promote the concentration of economic activities and centrifugal forces that oppose it. Of key interest is when a spatial concentration of economic activity is sustainable, and when a system without spatial concentration breaks down and concentration emerges. Combining formal theoretical models that include increasing returns to scale and computer simulations to study nonlinear dynamic properties, this work links urban, regional, and trade economics in a way that exceeds the dreams of the formal modelers of half a century ago. As was the case then, however, many geographers and others within the regional science community do not embrace this formal mathematical, theoretical mainstream economics approach. They are far more interested in the social, cultural, and institutional factors involved in spatial development and in the study of real places and real regional histories in contrast to abstract ones. The *Journal of Economic Geography* has served to encourage dialog among the different groups.

Also a recent development in economic growth theory, endogenous growth posited by Paul Romer has found strong interest in regional science. Endogenous theory argues that the legendary Solow residual is explained by local endogenous factors that drive innovation and technology change and thus growth. (The Solow residual refers to the large unexplained variance in his regression of national income on labor and capital. He suggested that this variance was due to technology.) As such it highlights the importance of local regional factors in innovation-driven growth and thus has helped drive a strong and growing interest in entrepreneurship and the innovative clustering of industry as factors that help explain local economic development and growth.

Methods of Regional Analysis

A different early quest of modern regional science was the creation of practical tools for the study of real places, and here regional science has had spectacular success. The input–output model attracted early attention. A series of regional input–output articles appeared in the *Review of Economics and Statistics* between 1951 and 1971. Their foci ranged from the theoretical specifications of the models and the definitions of concepts to studies of the nature of metropolitan economies, the location of industrial complexes, and the effects of arms reduction. This initial period culminated in the creation of two landmark regional input–output models constructed from survey-based data, the Philadelphia model of Isard and Thomas Langford, and the West Virginia model of William Miernyk. The next three decades focused on building and using models, with attention paid to the treatment of households and consumption, economic–demographic linkages, and strategies for building the models in a cost-effective way. Here too, progress exceeded the dreams of the 1950s, with regional input–output models now widely used for impact studies in the private and public sectors in many countries of the world. In fact, this method of regional analysis has become an industry with data and software readily available from commercial firms, most notably the IMPLAN system within the United States.

Econometric modeling similarly saw astonishing progress based on the pioneering work of Jean Paelinck in the Netherlands (noted as the father of spatial econometrics) and others in Europe, Japan, and the US. Interest in this methodology grew, eventually resulting in the formation of the Association of Spatial Econometrics established *c.* 2002 and the *Journal of Applied Spatial Econometrics* in 2005. Parallel and in concert with these developments other scholars such as Lawrence Klein sketched how regional econometric models might be developed as satellites of national models, and his student Norman Glickman (Glickman, 1971) developed a fully operational landmark model of the Philadelphia economy. Subsequently many others built regional econometric models as doctoral dissertations, one becoming the blueprint for the National Regional Impact Evaluation System of the US Department of Commerce. Today most states and many companies maintain such forecasting models. This method, too, has become an industry with many companies selling forecasts to private

subscribers. A particular noteworthy case is the eclectic REMI model of George Treyz, which grew from a design at a regional science meeting in 1978 into a widely used commercial product.

Modeling land use and transportation flows within a metropolitan region proved to be arguably the most ambitious search for practical methods, and the most spatially explicit. The intellectual scope of such modeling efforts is daunting: understanding the determinants of the location of industrial, commercial, residential, and other activities and of the movement of people among those locations. These models combined five elements: the theoretical urban economic framework of Alonso and Lowdon Wingo, mathematical programming methods to make them operational starting with the Herbert–Stevens model of land use, gravity models of spatial interaction eventually enriched by the entropy formulations of Alan Wilson, discrete choice statistical methods eventually incorporating McFadden's work, and the transportation forecasting framework established by Robert Mitchell and Chester Rapkin. For nearly five decades, university research groups, notably those led by Britton Harris, Alan Wilson, and David Boyce, have produced a sustained flow of dissertations and other contributions. Yet, unlike the cases of input–output and spatial econometric models, the pioneering research phase did not lead to widespread adoption in routine public and private practice. Dominant practice remains a set of incremental steps – predict population and employment change, decide (usually unaided by models) where those activities will locate, and then use transportation modeling software to forecast the flows among the locations. The research quest continues, large-scale operational models continue to be built (about a dozen were in use in the early 1990s), and the research leads to improvements in the transportation modeling software and other elements of the incremental approach.

Regional Economic Development and Policy

The basic quest here is to understand differences in regional growth and development and then use this knowledge to shape policy. During the early years of modern regional science these concerns attracted the attention of two more Nobel laureates in economics. Gunnar Myrdal was honored in 1974 for his "penetrating analysis of the interdependence of economic, social, and institutional phenomena." His work on economic theory and underdeveloped regions centered on the principle of cumulative causation, a 'vicious circle' of economic and noneconomic factors that led activities to cluster in certain regions and caused regional inequalities. Douglass North was honored in 1993 for "for having renewed research in economic history by applying economic theory and quantitative methods in order to explain economic and institutional change." He studied regional economic growth using exportable commodities or the export base as the key concept, pointing out the incentives regions have to reduce their processing and transportation costs to better the competitive position of their exports. An influential book by Michael Porter, *The Competitive Advantage of Nations* (1990), builds on these notions of clusters of activities and the competitiveness of export industries and finds a theoretical rationale in endogenous growth theory. Porter argues that national advantage derives from successful firms concentrating geographically within a country, their competitive success stimulated by their local (i.e., endogenous) environment, including via government policy at the regional and local level. An earlier formulation remains popular in regional policy. Based on the growth pole research initiated by Francois Perroux, governments concentrate investment in selected urban centers to stimulate the economies of their surrounding areas or draw population away from the crowded, larger metropolitan areas.

Policy and policy analysis are continuing and important parts of the regional economic development theme and draw not only on the above-referenced approaches to its study but to a large body of empirical research used to help advise policy. While policy has been a major focus of many conceptual and empirical studies in regional science, there was no specific policy-focused regional science journal until recently. In 2008, the RSAI established the *Journal of Regional Science Policy and Practice* as a primary outlet for policy-oriented studies. Further, the rise of importance of endogenous growth theory in regional science has led to growing interest and conceptual support in economic policy and practice at the local regional level and can be seen as one of the driving forces leading to the formation of this journal.

Other

Brief mention of some other work completes a broader picture of regional science. RSAI has awarded its Founder's Medal to Martin Beckmann for research in transportation network theory, location theory, and spatial economics; William Alonso for urban economics, spatial demography, and regional development; Jean Paelinck for methods of regional analysis, spatial econometrics, and regional policy; and David Boyce for transportation network models and urban transportation planning methods; Peter Nijkamp for wide and deep contributions to theory, methods, and policy contributions; Antoine Bailly for diverse contributions to scholarship, research, teaching, institution building, international relations, and leadership; and Arthur Getis for spatial statistics and geographic information science.

The three most cited articles in the *International Regional Science Review* are on population dispersal from major metropolitan regions internationally (Vining and Kontuly, 1978), intraurban residential mobility (Quigley and Weinberg, 1977), and the shift of the US population to nonmetropolitan areas (Beale, 1977). In the *Journal of Regional Science* they are on the distribution of residential activity in urban areas (Herbert and Stevens, 1960), determinants and consequences of migration (Greenwood, 1985), and an efficient algorithm to solve the Weber location problem (Kuhn and Kuenne, 1962). In *Regional Science and Urban Economics*, they are on the baby boom and the housing market (Mankiw and Weil, 1989), the demand for housing characteristics (Follain and Jimenez, 1985), and publicly provided inputs and economic growth (Garcia-Mila and McGuire, 1992). In the *Annals of Regional Science*, they are on spatial statistical analysis (Anselin and Getis, 1992), regional inequality (Menczes et al., 2012), and regional disparities in Europe (Ertur and Koch, 2006). The bibliography includes well-cited books and recent overviews of aspects of regional science.

Regression Discontinuity Design

Joseph C Cappelleri, Pfizer Inc, Groton, CT, USA
William M Trochim, Cornell University, Ithaca, NY, USA

© 2015 Elsevier Ltd. All rights reserved.
This article is a revision of the previous edition article by W. M. Trochim, volume 19, pp. 12939–12945, © 2001, Elsevier Ltd.

Abstract

The regression-discontinuity (RD) research design assigns participants to treatment groups solely on the basis of a pretreatment cutoff score, allowing the relative effect of treatment to be studied in participants who most need or deserve a particular treatment. In this article a brief history of the design is given, the basic RD design structure is described, design considerations and variations are highlighted (on cutoff selection, assignment variations, multiple cutoff points, multiple assignment measures, treatment variations, and posttreatment measurement variations, internal validity, measurement error, statistical power), and recent methodological developments are presented (on nonparametric statistical analysis, the 'fuzzy' RD design, and design variations).

Definition

The regression-discontinuity (RD) research design is a quasi-experimental method that can be used to assess the effects of a treatment or intervention. Unique to the RD design is that participants are assigned to groups solely on the basis of a pretreatment cutoff score. The name 'regression-discontinuity' comes from the fact that a treatment effect appears as a 'jump' or discontinuity at the cutoff point in the regression function linking the assignment variable to the outcome. In its simplest form, the design has a pretest or pretreatment (the assignment variable) measure, two groups (those scoring above and below the cutoff), and a posttest or posttreatment (the outcome) measure. More complex variations are also possible.

To many, the RD design initially seems counterintuitive. Using a cutoff to assign participants to the program (or treatment) group and comparison (or control) group creates a pretreatment group nonequivalence that seems like it should lead to selection bias. While the design does induce initial nonequivalence, it does not necessarily lead to biased treatment effect estimates. Instead of assuming pretreatment equivalence (in measured and unmeasured means and variances) as the randomized experiment does, the RD design assumes the two groups are equivalent in their pre–post regression functions in the absence of a treatment effect. This assumption can be tested.

The major attraction of RD designs is that they can be used to estimate the effects of treatments given to those who most need or deserve them – provided that need or merit is determined using a qualification score on the pretreatment assignment variable (i.e., the cutoff) to experimental conditions, and nothing else. Because the design does not require that some needy or deserving individuals get assigned to a no-treatment or comparison group, in some settings it may have ethical advantages over experiments for assessing treatment effects.

History

In a 2008 special issue on RD methodology in the *Journal of Econometrics*, Cook (2008) provided a detailed and comprehensive history of the RD design in three academic disciplines – psychology, statistics, and economics – which covers the reinvention of the design across these disciplines and the differential waxing and waning by discipline (Cook, 2008). Applications of the RD design have also expanded to the health sciences (Trochim, 1990; Trochim and Cappelleri, 1992; Cappelleri and Trochim, 1994, 1995; Finkelstein et al., 1996a, 1996b; Linden et al., 2006; Zuckerman et al., 2006). Many noteworthy contributions using the RD design have been made in the 1960s (Thistlethwaite and Campbell, 1960), 1970s (Goldberger, 1972; Wilder, 1972; Tallmadge and Horst, 1976; Rubin, 1977), 1980s (Berk and Rauma, 1983), 1990s (Cappelleri et al., 1991; Trochim et al., 1991; Mark and Mellor, 1991; Cappelleri et al., 1994; Reichardt et al., 1995; Aiken et al., 1998; Angrist and Lavy, 1999; Berk and de Leeuw, 1999), and 2000s (Van Der Klaauw, 2002; DiNardo and Lee, 2004; Card and Shore-Sheppard, 2004; Jacob and Lefgren, 2004; Ludwig and Miller, 2007; Matsudaira, 2008; Wong et al., 2008; Van Der Klaauw, 2008; Lalive, 2008; Lee, 2008; Gamse et al., 2008).

A growing number of books have featured the RD design. It was first discussed by Campbell and Stanley (1963) and in greater detail in books on social experimentation (Riecken et al., 1974; Bennett and Lumsdaine, 1975). Later the RD design was extensively discussed in texts on quasi-experimentation (Cook and Campbell, 1979; Shadish et al., 2002) and on evaluation (Judd and Kenny, 1981; Mohr, 1995). Trochim (1984) wrote the first and, to date, only book devoted exclusively to the method. With the dawning of the twenty-first century several books discussed the RD design, presenting updates on its methodology and applications, including (but not limited to) books by Fleiss et al. (2003), Senn (2007), Angrist and Pischke (2009), and Murnane and Willett (2011).

The Basic RD Design Structure

Figure 1 shows an example of the RD design using simulated data to depict the case of a compensatory treatment – perhaps a reading program designed to help students who initially score poorly (defined as below the pretest cutoff) on a standardized reading measure. The figure is a standard bivariate plot of

Figure 1 Basic regression-discontinuity design for a compensatory treatment showing a positive effect.

posttest and pretest for 500 simulated participants. Data points for the treatment recipients are represented with '+,' while the comparison cases are 'o.' The cutoff value in this example occurs at the middle of the pretest distribution (pretest = 50) and is indicated by the vertical line. All students scoring below 50 are defined as needing compensatory training and get the treatment, while the remaining (i.e., those to the right of the cutoff) are assigned to the comparison (control) group.

The solid lines represent the straight-line regression of posttest on pretest for each group. In the absence of a treatment effect, the critical assumption is that the regression line in the comparison group would continue to the left of the cutoff into the treatment group region, as indicated by the heavy dashed line. That is, if the reading program does not work, then the observed treatment group regression line would be where the dashed line is. The fact that the observed treatment group line is displaced from this 'expected' line suggests a treatment effect – treatment group participants scored higher on the posttest (i.e., vertically) than would have been predicted from the comparison group pre–post relationship. The size of the treatment main effect is estimated as the vertical jump or *discontinuity* between the *regression* lines at the cutoff, hence the name *regression-discontinuity*. Assuming that higher scores on both measures indicate better performance, one can conclude from the figure that the treatment improved participant performance by the amount of the vertical discontinuity.

In experimental designs random assignment assures that the treatment and comparison groups are initially probabilistically equivalent. Posttreatment differences can be then attributed to the intervention. In the RD design one obviously does not expect this kind of equivalence. Instead, it is assumed that the *relationship* between the assignment variable and the outcome is equivalent for the two groups – that is, the same continuous regression line describes both groups. Thus, interpretation of the RD design depends mostly on two factors: (1) that no alternative cause could induce a discontinuity at the cutoff and (2) that we can perfectly model the pre–post relationship. These issues, particularly the second one, constitute the major problems in the statistical analysis of the RD design (Trochim, 1984, 1990; Winship and Morgan, 1999).

Design Considerations and Variations

Selection of the Cutoff

The RD design requires that the assignment and outcome measures be of sufficient quality of measurement to warrant an appropriate regression analysis. The choice of cutoff value can be made solely on the basis of available resources. For instance, if a program can handle only 25 persons and 70 apply, then a cutoff point can be selected that distinguishes the 25 most 'needy' persons from the rest. The cutoff can also be chosen on substantive grounds. If the assignment measure is an indication of severity of illness measured on a one to seven scale, relevant experts might contend that all those scoring an average of five or more are ill enough to deserve treatment. Therefore, a theoretically justified cutoff of five could be used.

Assignment Variations

A 'sharp' RD design has its pretreatment cutoff value followed perfectly, without exception. While the use of a pretreatment cutoff distinguishes the RD design, it is often difficult to implement. In principle it does not allow room for professional judgment or discretion. In fact, the design does not preclude incorporating such judgment so long as it can be quantified or explicitly accounted for when specifying the cutoff value.

Violation of the assignment rule leads to 'misassignment' and to what is often termed the 'fuzzy' RD design. Typically, misassignment is most prevalent for 'close call' cases that fall near the cutoff. For instance, teachers or parents may successfully argue that students who just miss the cutoff for a novel compensatory tutoring program should be assigned to it based on grounds other than their assignment score. In the fuzzy RD case, standard analyses will yield biased estimates of treatment effect. While statistical procedures for dealing with

misassignment have been suggested (Trochim, 1984), misassignment is better avoided if possible.

Multiple Cutoff Points

RD designs are not limited to a single cutoff value. In the absence of treatment the assumption is that the pre–post relationship can be described as a single continuous regression line extending over the entire range of the assignment scores. Even when multiple cutoff points are used, the comparison group's pre–post relationship is still used as the counterfactual for projecting where other groups' regression lines should be if there is no treatment effect.

The simplest multiple cutoff case involves two cutoff scores. In this variant, persons scoring above the higher cutoff might be assigned to one treatment, those scoring below the lower cutoff to another, and those scoring within the cutoff interval might be controls. The assignment of treatments to each part of the assignment distribution can be made in alternative ways, including by random assignment. For instance, individuals within the interval between the two cutoffs could be randomly assigned to conditions, while those scoring below the lower cutoff and above the upper cutoff are analyzed as from an RD design (Boruch, 1973). Trochim and Cappelleri (1992) discuss four other ways of coupling random assignment to RD design features.

Multiple cutoff points are also involved in designs where the treatment is implemented a series of times (i.e., in phases), perhaps beginning with the most needy before successively giving it to those less needy. In the first phase, one uses a single cutoff value, assigning those most in need to the treatment and then measuring posttreatment performance. Then, the cutoff value would be moved to include the next most needy group on the assignment measure. Eventually, everybody could receive the treatment, but in groups ordered by need and phase. This is particularly useful in organizations seeking to 'roll out' a treatment over time, but eventually serving all.

Multiple Assignment Measures

The requirement of strict adherence to the cutoff criterion entails a single quantitative indicator. When this does not capture the degree of pretreatment need well, Trochim (1990) discusses two multivariate strategies. The first involves the use of several separate measures, each having its own cutoff value. This is most feasible when a prospective participant must meet the different cutoff criteria on measure 1 'and' measure 2 'and' measure 3, and so on. Less feasible is an 'or' rule when assignment depends on meeting a fixed number of criteria from a larger set – say, 5 of 10. The second involves assignment according to a new variable that is a composite of several individual measures. Using multiple measures this way can help incorporate more judgment into a quantitative assignment strategy.

Treatment Variations

When treatment comparisons are absolute, the control (or comparison) group receives no formal or placebo treatment. When they are relative, the comparison group receives an alternative treatment, very often the current standard treatment to which a new one is to be compared.

An advantage of the RD design is that it enables assignment of progressively riskier treatments to those in greater need. Assume three treatment programs: the standard plus two increasingly riskier experimental ones. It is then possible to have two cutoff points and to assign the riskiest treatment to the neediest patients, the least risky (i.e., standard) treatment to the least needy, and the moderately risky treatment to those falling between the two cutoffs. (If no a priori basis exists for making risk judgments, an alternative would be to use a single cutoff and to assign those least in need to standard treatment while randomly assigning those on the other side of the cutoff into one of the two experimental conditions.) RD designs are flexible for examining treatment variations.

Posttreatment Measurement Variations

In RD designs, pre and post measures do not have to be on the same type of measure. For instance, one might assign persons to a health education treatment on the basis of household income but then examine its effects on attitudes toward health; here the assignment variable is an economic indicator and the outcome is a cognitive one.

The RD design is not restricted to a single outcome, and for each posttreatment measure there can be a separate RD design and analysis. However, it will often be useful to create an aggregate outcome or outcomes. For instance, we may have many knowledge items that are scaled to give a total (aggregate) score, with subtest scores for mathematical reasoning, computational skills, verbal reasoning, analogies, and so on. We might then conduct separate analyses for both the total score and each subtest.

Outcome measures need not be continuous normal variables. While such distributions facilitate RD analysis, they are not necessary for it. For example, Berk and Rauma (1983) evaluated the effects of a California law that extended unemployment benefits to released prisoners who had not previously been eligible. In order to qualify, prisoners had to earn at least $1500 working in the prison over the 12 months prior to release. Would extending these benefits reduce subsequent recidivism? A dichotomous outcome was created with 1 indicating recidivism and 0, staying out of prison. To analyze this outcome, Berk and Rauma (1983) relied on a linear random utility model related to the binary logit model.

Internal Validity

Internal validity refers to the degree to which causal inference is reasonable because alternative explanations for an apparent treatment effect can plausibly be ruled out. The RD design is very strong with respect to internal validity because the process of selection into treatments is fully known and only factors that would serendipitously induce a discontinuity in the pre–post relationship at the cutoff can be considered threats. However, validity also depends on how well the analyst can model the true pre–post relationship so that underlying nonlinear relationships do not masquerade as discontinuities at the cutoff point.

The RD design does not yield biased estimates of the treatment effect when the assignment variable is measured with

error (Cappelleri et al., 1991; Trochim et al., 1991). The reason such error does not induce bias here, although it does in other quasi-experiments, is that assignment to treatment is by the fallible assignment variable and not by some latent underlying selection process, as happens in quasi-experiments.

Statistical Power

It takes approximately 2.75 times as many participants in an RD design to achieve statistical power comparable to a simple randomized experiment, assuming equal numbers assigned to the treatment and control groups (Goldberger, 1972). When RD is combined with random assignment within an interval around this cutoff, 2.48 times the number of respondents are needed if 20% of participants are randomized, 1.96 times with 40% randomization, 1.46 with 60%, and 1.14 with 80% (Cappelleri and Trochim, 1994, 1995, 2010).

Parametric Analysis

Assumptions of RD Analysis

Five central assumptions must be made in order for responsible analysis of data from an RD design:

1. The cutoff criterion: The cutoff criterion must be followed without exception. Otherwise, unless some valid adjustment is made, a selection threat arises, and estimates of the treatment effect are likely to be biased.
2. The pre–post distribution: The true pre–post distribution must be known and correctly specified as linear, polynomial, logarithmic, or the like. Reichardt et al. (1995) point out the difficulties in specifying the appropriate model, especially when some curvilinearity exists in the pre-post relationship.
3. Comparison group pretest variance: There must be a sufficient range of pretest values in the comparison group to enable adequate estimation of the pre–post regression line for that group. Variability in the treatment group is also desirable, although not strictly required because one can project the comparison group line even to a single treatment group point.
4. Continuous pretest distribution: Both groups must come from a single continuous pretest distribution. In some cases one might find intact groups that serendipitously divide on a measure so as to imply some cutoff (e.g., patients from two different geographic locations). However, such naturally discontinuous groups would confound geography with treatment and should not be used.
5. Treatment implementation: It is assumed that the treatment is uniformly delivered to all recipients – that is, they all receive the same dosage, length of stay, amount of training, or whatever. If not, it is necessary to model explicitly the treatment as implemented, thus complicating the analysis considerably.

A Model for the Basic RD Design

The model presented here is for the basic RD design. Given a pretreatment assignment measure, x_i, and a posttreatment measure, y_i, the model for the expected value (E) of y_i can be stated as follows:

$$E(y_i) = \beta_0 + \beta_1 z_i + \beta_2 \tilde{x}_i + \beta_3 \tilde{x}_i z_i + \cdots + \beta_{n-1} \tilde{x}_i^s + \beta_n \tilde{x}_i^s z_i$$

where

$\tilde{x}_i$ = pretreatment measure for individual i minus the cutoff value (i.e., $\tilde{x}_i = x_i - x_0$)
y_i = posttreatment measure for individual i
z_i = assignment variable (1 if treatment participant; 0 if comparison participant)
s = the degree of the polynomial for the associated $\tilde{x}_i$
β_0 = parameter for comparison group intercept at cutoff x_0
β_1 = treatment effect parameter
β_2 = linear slope parameter
β_3 = linear interaction parameter
β_{n-1} = parameter for the sth-order polynomial
β_n = parameter for the sth-order polynomial interaction term

The major null hypothesis of interest H_0: $\beta_1 = 0$ is tested against the alternative H_1: $\beta_1 \neq 0$. The model estimates both main and interaction effects at the cutoff point in order to examine changes in means and slopes. It postulates a polynomial pre–post relationship. It also requires subtracting the cutoff score from each pretest score. The term $\tilde{x}_i$ has a superscript tilde to indicate this transformation of the pretest x_i.

Finally, the model allows for any order of polynomial function (although certain restrictions are made in specifying the function as described below). Thus, the true pre–post relationship can in theory be linear, quadratic, cubic, quartic, and so on.

In the simplest model with no interaction term, which includes only treatment and the pretest (pretreatment) assignment covariate as predictors, the treatment effect (β_1) is constant across pretest assignment scores and, therefore, the same at the cutoff score as any other pretest score on the assignment continuum. In a model with a linear treatment-by-pretest interaction, the treatment effect is no longer constant across the (pretest) assignment continuum but depends linearly on the value of the pretest assignment score, allowing for the population slopes of the pre–post relationship to differ on opposite sides of the discontinuity.

Model Specification

The key analytic problem is correctly specifying the model for the data – in this example, as a polynomial model. No simple or mechanical way exists to determine definitively the appropriate model. As is the case with any judicious statistical modeling, the RD analysis requires judgment and discretion, along with conducting multiple analyses based on different assumptions about the true pre–post relationship.

Steps in the Analysis

Recall what data the basic RD design provides on each unit. There is a pretest assignment value x_i in the model. Knowing this and the cutoff value allows creating a new variable z_i, which is equal to 1 in the treatment group and 0 if not. Finally, there is a posttest (or posttreatment) score labeled y_i in the

model. Given the variables x_i, z_i, and y_i, the steps to be followed in the polynomial analysis are as follows:

1. Transform the pretest

The analysis begins by subtracting the cutoff value from each pretest score thus creating the term $\tilde{x}_i$ as in the model. This sets the intercept equal to the cutoff so that estimates of effect are made at the cutoff rather than at $x_i = 0$.

2. Examine the relationship visually

It is important to determine whether there is any visually discernible discontinuity at the cutoff. It could be a change in level, slope, or both. If a discontinuity is visually clear at the cutoff one should not be satisfied with analytic results that indicate no effect. However, if no discontinuity is apparent, variability in the data may be masking an effect, and one must attend carefully to the analytic results.

The second thing to look for is the degree of polynomial that may be required as indicated by the overall slope of the distribution, but particularly in the comparison group part. A good approach is to count the number of flexion points (how often the distribution 'flexes' or 'bends'). A linear distribution implies no flexion points, while a single flexion point would indicate a quadratic function, and so on, such that the estimated polynomial is equal to one order less than the total number of flexion points (i.e., with two flexion points one would hypothesize a cubic or third-order polynomial). This information is used to specify the initial model.

3. Create higher order terms and interactions

Depending on the number of flexion points, create transformations of the transformed assignment variable $\tilde{x}_i$. The rule of thumb is to go two orders of polynomial higher than indicated by the number of flexion points. Thus, if the bivariate relationship appeared linear (i.e., no flexion points), one would want to create transformations up to a second-order $(0 + 2)$ polynomial. The first-order polynomial already exists in the model $(\tilde{x}_i)$, and one would only have to create the second-order polynomial by squaring $\tilde{x}_i$ to obtain $\tilde{x}_i^2$. For each transformation of $\tilde{x}_i$ one also creates the interaction term by multiplying the polynomial by z_i. In this example there would be two interaction terms: $\tilde{x}_i z_i$ and $\tilde{x}_i^2 z_i$. If there seems to be two flexion points in the bivariate distribution, one would then create transformations up to the fourth $(2 + 2)$ power and their interactions. This rule of thumb errs toward overestimating the true polynomial function needed, for reasons outlined in Trochim (1984).

4. Estimate the initial model

The true analysis can now begin. One simply regresses the posttest scores, y_i, on $\tilde{x}_i$, z_i and all higher order transformations and interactions created in step 3 above. The regression coefficient associated with the z_i term (i.e., the group membership variable) is the estimate of the main effect of the treatment. If there is a vertical discontinuity at the cutoff it will be estimated by this coefficient. One can test the significance of the coefficient (or any other) by constructing a standard t-test. If the analyst correctly overestimated the polynomial function required to model the distribution at step 3, then the treatment effect estimate will be unbiased. However, by initially including terms that may not be needed in the true model, the estimate is likely to be inefficient, that is, standard error terms will be inflated and statistical significance underestimated. However, if the coefficient for the effect is highly significant in this initial model, it would be reasonable to conclude there is an effect. Interaction effects can also be examined. A linear interaction is implied by a significant coefficient for the $\tilde{x}_i z_i$ term.

5. Refine the model

The procedure described thus far is conservative, designed to reduce the chances of a biased treatment effect estimate even at the risk of increasing the error of the estimate (Trochim, 1984). Therefore, on the basis of the results of step 4 one might wish to attempt to remove apparently unnecessary terms and reestimate the treatment effect with greater efficiency. This is tricky and should be approached with caution lest it introduces bias. One should certainly examine the regression results from step 4, noting the degree to which the overall model fits the data, the presence of any insignificant coefficients, and the pattern of residuals. One might examine the highest order term in the current model and its interaction. If both coefficients are nonsignificant, and the goodness-of-fit measures and pattern of residuals indicate a good fit, one might then drop these two terms and reestimate the model. One would repeat this procedure until (1) all the coefficients are significant, (2) the goodness-of-fit measure drops appreciably, or (3) the pattern of residuals indicates a poor fit.

Analyses with Multiple Cutoff Points

The basic model described above can be applied directly when multiple cutoff points are used and random assignment is followed within cutoff intervals. If assignment within intervals is nonrandom, one must also address the potential for selection bias in the analysis. When multiple cutoffs are used to distinguish separate treatments (i.e., multiple treatments are not assigned within the same cutoff interval), one would have to construct multiple treatment assignment variables for the analytic model (e.g., z_1, z_2, z_3) and all necessary interaction terms. Clearly, as more cutoffs and groups are added, model specification becomes more complex.

Analyses with Multiple Assignment Measures

Imagine having multiple measures, each with its own cutoff. Each assignment measure is then transformed by having its own cutoff value subtracted from it to create $\tilde{x}_i$. The analysis would then include all transformed assignment measures, group membership, higher order terms, and interactions. For the simple first-order (or linear) case, one could use the following model:

$$E(y_i) = \beta_0 + \beta_1 z_i + \beta_2 \tilde{x}_{1i} + \beta_3 \tilde{x}_{2i} + \beta_4 \tilde{x}_{3i} + \beta_5 \tilde{x}_{1i} z_i + \beta_6 \tilde{x}_{2i} z_i + \beta_7 \tilde{x}_{3i} z_i$$

This model does not include any two-way assignment variable multiplicative terms (e.g., $\tilde{x}_{1i} x_{2i}$ or $\tilde{x}_{1i} x_{2i} z_i$) or any three-way assignment variable multiplicative terms (e.g.,

$\tilde{x}_{1i}x_{2i}x_{3i}$ or $\tilde{x}_{1i}x_{2i}x_{3i}z_i$), but such an assumption may be reasonable where primary interest is in estimating β_1, the treatment effect at the cutoff, and not interactions. Clearly, however, the use of multiple assignment variables with higher order polynomial models will quickly lead to an unwieldy analysis.

The situation is simpler when multiple assignment variables are rescaled to reflect the number of assignment variables on which a person meets the criterion (e.g., on 5 of 10). This number then becomes the x_i variable, and one would conduct the basic analysis described earlier. When multiple assignment variables are combined into a single index, the analysis is also a straightforward application of the basic procedures described initially.

Recent Methodological Developments

Nonparametric Statistical Analysis

As noted, the most serious limitation of RD designs is the possible sensitivity of the functional form between the posttest outcome and pretest assignment covariate. Traditionally, parametric models with polynomial regression have been used to analyze RD design. If the extrapolation beyond the cutoff score is not adequate, then what masquerades as a jump due to treatment might simply be a nonlinear relationship showing no real treatment effect.

To reduce the likelihood of such mistakes, economists have proposed and implemented nonparametric approaches that look only at the data in the neighborhood around the cutoff score (Hahn et al., 2001; Ludwig and Miller, 2007; Imbens and Lemieux, 2008; Angrist and Pischke, 2009). Comparisons of average outcome scores in small-enough neighborhoods to the left and right of the cutoff can be estimated in a way that does not depend on the correct functional form. Instead of providing a constant treatment effect generalizable across all values of the pretest assignment covariate (in the case of a model with no pretest-treatment interaction), as occurs with the parametric approach, the average treatment effect in the nonparametric approach is restricted to (and conditional on) the cutoff score.

The nonparametric approach to RD requires good estimates of the mean posttreatment scores in small neighborhoods to the immediate right and left of the cutoff. However, such estimation can be tricky. One notably conspicuous problem is the sparse or limited data in a small neighborhood of the cutoff means. Local linear regression, a nonparametric smoothing technique, has been proposed to address the typically relatively scant data around the cutoff means (Hahn et al., 2001; Imbens and Lemieux, 2008; Angrist and Pischke, 2009).

Nonparametric RD estimation is not without its shortcomings (Bloom, 2012). The method requires very large samples to provide an adequate number of observations in the two bandwidths adjacent to the cutoff point. Another limitation is the potential sensitivity of nonparametric estimations to the choice of bandwidth. A trade-off is needed between, on the one hand, introducing bias from a bandwidth that is too wide and, on the other hand, losing precision from a bandwidth that is too narrow. The most widely used empirical approach for making such a trade-off is cross-validation (Imbens and Lemieux, 2008).

Fuzzy RD Design

As noted previously, a violation of the assignment rule to treatment and comparison groups results in a fuzzy RD design. Here external factors result in individuals being placed in one group when they should have been placed in the other group according to their pretreatment assignment score. A conventional analysis of a fuzzy RD design, which does not account for this misassignment, would result in a biased treatment effect. Under certain circumstances, a potential solution to obtain an unbiased treatment effect in the fuzzy RD design is to apply the technique of instrumental variables (Angrist and Pischke, 2009; Murnane and Willett, 2011). Here the pretreatment (or pretest) assignment measure can serve as a credible instrumental variable for actual group membership if this pretreatment assignment measure predicts actual group membership and, at the same time, is not directly related to the posttreatment measure.

A two-stage least squares regression method (a parametric approach based on ordinary least squares) to instrumental variable estimation has been proposed and applied to analyze the fuzzy RD design (Jacob and Lefgren, 2004; Angrist and Pischke, 2009; Murnane and Willett, 2011). The nonparametric version of fuzzy RD consists of instrumental variable estimation in a small neighborhood around the discontinuity. Hahn et al. (2001) developed a nonparametric procedure for instrumental variables using local linear regression around the cutoff, which was applied to estimate the effect of class size on childrens' test scores (Angrist and Lavy, 1999).

In research related to instrumental variables, Battistin and Retorre (2008) and Bloom (2012) provide additional insights and expanded paradigms for fuzzy RD designs. They provide conditions that are required to make fuzzy RD designs valid in identifying average treatment effects.

Design Variations

Building on previous research on logistical and analytical issues of RD designs with varying amounts of randomization (Trochim and Cappelleri, 1992; Cappelleri and Trochim, 1994, 1995, 2010; Cappelleri et al., 1994), Mandell (2008) provides extended formulations and insights into this hybrid design in which cutoff-based assignment and random assignment are combined depending on values of the pretreatment assignment indicator to experimental conditions. Different hybrid designs can have varying degrees of randomization and discontinuity. They entail smaller sacrifices in statistical efficiency than the basic or pure RD design (which has no randomization embedded within it) and are also likely, in certain circumstances, to be judged considerably fairer than a true randomized experiment and possibly even a pure RD design.

Another variation is the clustered RD design where groups (rather than individuals) are assigned to an intervention. Considerably more methodological work has been performed on the design and analysis of RD designs when treatments are applied to individuals (Shadish et al., 2002;

Imbens and Lemieux, 2008) than to groups. More recently, however, increased methodological research on RD designs has been applied in the context of community or group-level interventions. The clustered RD design, for example, was the primary design to evaluate the federal education program mandated in the No Child Left Behind Act of 2001 (Gamse et al., 2008). Motivated by 'No Child Left Behind,' Schochet (2009) examined the statistical power under such clustered RD designs (without randomization) using techniques from the causal inference and hierarchical linear modeling literature. The main conclusion is that three to four times larger samples are typically required under the clustered RD design than under the clustered randomized design to achieve estimates of effects with the same level of precision.

Pennell et al. (2011) noted that designs in education are often quite different from designs used in public health and investigated the design and analysis of clustered RD designs in which a varying proportion of groups is randomized. These researchers extend upon previous work to consider analysis, statistical power, and sample size implications of RD designs in community-based intervention studies in public health. In doing so they examined the power of these designs as a function of the intraclass correlation, number of groups, and number of members per group and compared the results with the traditional group randomized trial.

Variations on the RD design can also be distinguished by the nature of the assignment. Research on the RD design has typically focused on applications with a single assignment variable. In many settings, however, it may be more appropriate to impose cutoffs on several assignment variables in defining a set of different treatments. For instance, cutoffs on two assignment variables in a basic RD design would result in two dimensions with four treatment regions. By using regression to model the response surface in each region, and obtaining predicted values along each of the discontinuity edges, Papay et al. (2011) show how to generalize the basic RD design to include multiple assignment variables simultaneously and to estimate the effects of several treatments.

Conclusions

From a methodological point of view, inferences drawn from a well-implemented RD design are considered comparable in internal validity to conclusions from randomized experiments. However, the lower statistical efficiency of RD designs, and the resulting sample size demands, may limit the design's utility. From an ethical perspective, RD designs are compatible with the goal of getting the treatment to those most deserving or in need. It is not necessary to deny the treatment from potentially deserving recipients simply for the sake of a scientific test. From an administrative viewpoint, the RD design may be directly usable when allocation formulas are the basis for assigning treatment or treatments.

With all these considerations in mind, the RD design must be used judiciously. In general, the randomized experiment is still the method of first choice when assessing causal hypotheses (Cappelleri and Trochim, 2010). However, where they are ruled out as impractical, the RD design should be considered as a practical high-quality alternative.

Abstract

Regulation is the practice of shaping significant institutions, particularly businesses, so as to take into account social purposes that might not be taken into account in the ordinary process of doing business. According to one definition, it is the imposition of legal orders on those engaged in economic activity. The social purposes of regulation can range from promoting economic efficiency, or protection from harm or risk, to promoting diversity or equity. States regulate capitalist enterprises within capitalist or mixed economies – controlling aspects of, for example, the price of services, entry into occupations, and the products and processes of businesses.

Regulation is the practice of shaping significant institutions – particularly business, but also industry, universities, governments – so as to take into account social purposes. Regulation often aims to promote some social concerns that might not be taken into account in the ordinary process of doing business. According to one definition, it is the imposition of legal orders on those engaged in economic activity (Kagan, 1978). States regulate capitalist enterprises within capitalist or mixed economies, often focusing on the price of services, entry into occupations, and the products and processes of businesses.

Cross nationally and across different policy areas, various institutions take on the task of regulation, including government boards, inspectorates, specialized courts, and independent commissions. How states are organized shapes the processes of regulation: to what extent courts are involved, how open procedures designing regulation are to interest group participation, who may be challenged in litigation. With the increasing proliferation of issues that cross or transcend national borders – immigration, climate change, and financial transactions being only the most obvious – has come global coordination of regulation. While much of this early coordination was informal, more formal systems of global regulation are increasingly emerging in arenas outside the state. Whether global or national, however, much regulation is constituted in the ordinary decisions of case-level officials. The meaning of those decisions requires attention to the organizational context in which they are made, not just the broader choices states have made in statutes or international agreements. In the last 10–15 years, regulation has become more important in developing countries, at global and transnational levels, and in nonstate settings.

Emergence and Justification

Bureaucratic regulation of industries emerged in the nineteenth century with the rise of industrial capitalism and the bureaucratic division of labor. Britain established a factory inspectorate for the textile industry as early as 1832. The use of inspectorates to address the more dangerous conditions at work – in match factories, in tenement labor – expanded dramatically throughout the Western world in the 1890s (Rodgers, 1998).

Regulation has proven to be at least partly reversible: central trends in capitalist economies during the 1970s and 1980s included both privatization of state-owned industries (see e.g., Graham and Prosser, 1988; Pistula and Rasmussen, 1990) and political pressure toward deregulating the already regulated industries (Derthick and Quirk, 1985; Harris and Milkis, 1996).

Economists have thought it important to explain why regulation is necessary within a capitalist economy, given that neoclassical economic theory holds that social purposes are best accomplished by markets. The importance of neoclassical theory has meant that advocates and critics of regulation have also expended effort understanding the justifications (see e.g., Breyer, 1982). Justification has sometimes centered on the concept of 'externalities.' A market requires that business pays for some components, for example, steel in manufacturing a car. However, the manufacturer does not have to buy the air that it pollutes in the process of making cars, and in turn, neither do consumers who drive the cars. In the United States in the 1960s and 1970s in particular, concern about the inability of companies to take into account the social costs of doing business was used to justify regulating products and processes in manufacturing.

In addition to regulating products and processes, governments regulate price and entry: the price that an industry may charge and the requirements to enter into the business. The justification of price and entry regulation does not rely upon the concept of externalities. Rather, the argument is that some industries take on the characteristics of monopoly, whether as a natural monopoly or because there are very high barriers to entry. For example, it could be inefficient to have multiple railways competing against each other since the costs of laying railroad track are very high. What is more, because it is expensive to build a railway, it is extremely difficult to enter the business, which means that the competition that is supposed to ensure that prices and services are responsive to consumer demand does not exist. Without competition, railroads could charge what they would for services. Thus railroads, the first industry subject to national bureaucratic regulation in the United States, would charge more for short-haul than for

long-haul trips because there was much less competition in short haul (Skowronek, 1982). Economists also note the importance of 'network effects' in monopoly. If the exchange of information is facilitated by having compatible computer systems, each person buying a computer system has an incentive to buy one compatible with those people already have, whether or not that is the best system. Advocates assert that professions like medicine and law require regulation because expertise is required to assess whether the profession is being practiced correctly. Consumers cannot assess whether a surgeon knows what he or she is doing until it might be too late.

These justifications for regulation have been subject to serious critique from those who believe that markets should be unregulated and from those who believe that regulation is ineffective because industries have special access to the state not shared by their workers or customers (Derthick and Quirk, 1985). In this view, regulatory bureaucracies, designed to incorporate public concerns into capitalist economies, become 'captured' by the industries they are to regulate. The regulatory bureaucracies then act largely to insulate the industries from competition and protect their interests. Sometimes that has happened by design: railroad regulators meant to maintain and steady the railroad industry. In the late nineteenth century, railroads in the United States wanted to be regulated to moderate the incentives to cut prices that were putting railroads out of business (Skowronek, 1982). In France, *notaires* welcome regulation to preserve their monopoly on drawing up legal contracts; opening that monopoly would have meant decreasing income as a result of competition (Suleiman, 1987).

Economists call the effort to gain protection from the market by legislative or bureaucratic intervention 'rent-seeking behavior' – that is, an effort to gain a return beyond what is required to keep one in the business – and many have argued that rent seeking is the heart of regulation. For example, lawyers benefit from the licensing of lawyers; it restricts the numbers of lawyers available and thereby maintains a higher price than would be the case if anyone could practice law. The claim that regulation protected inefficient industries from competition and used state power to keep prices artificially high provided a substantial part of the support for deregulation in the United States in the late 1970s and 1980s (Derthick and Quirk, 1985; Harris and Milkis, 1996).

While the United States developed regulatory institutions in a context of mainly private ownership of industries, in other nations, critiques of state ownership of industries led to privatization, which in turn entailed regulation (Graham and Prosser, 1988). During the 1980s and 1990s in Europe and the 1990s and 2000s in the developing world (Jordana and Levi-Faur, 2006; Minogue and Carino, 2006; Dubash and Morgan, 2013), regulatory agencies have proliferated. Their emergence and justification have been linked to purposes of both promoting economic efficiency (especially in essential services in both Europe and the developing world) and protection from risk or harm (especially in environmental or health and safety regulation in Europe). The importance of protective regulation can be seen by noting that the strength of the proenvironmental regulation lobby meant that environmental deregulation did not go far even in the United States (Harris and Milkis, 1996). Those advocating a more market-based approach in pollution rights gained recognition in Clean Air Act Amendments, and more recently in emissions trading regulatory schemes, but government officials remain deeply involved in regulation (Harris and Milkis, 1996; Ureta, 2013). Social solidarity and human rights have also provided justifications for the emergence of many regulatory regimes in recent years (Prosser, 2010).

Institutions that Regulate

Regulatory institutions vary considerably and all have different styles. Courts, legislatures, local governments, marketing boards, bureaucratic agencies, and (more indirectly) interest groups all can impose, and have imposed, orders on capitalist enterprise. In the United States before the Civil War, rather than relying on negotiations between business and bureaucrats, or on rules from bureaucrats that were enforced in the courts, the United States relied on courts – largely state courts – to enforce statutes or common law duties. By the late nineteenth century, most US states as well as the United Kingdom had instituted some bewildering array of boards, commissions, and special courts to ensure that a broader public interest was taken into account.

The first US federal regulatory agency, the Interstate Commerce Commission, was created in 1887. It was unusual in that it established an agency independent of immediate control by ministers, responsible for making a framework of policy through trial-type procedures, with decisions that could be appealed to general jurisdiction courts (Baldwin, 1985: p. 7). The United States' official regulatory procedure is more rule oriented than those in other Western industrialized states, and courts are more deeply involved in making policy. The American system also allows for much more public participation and opportunity to argue against regulations both within an administrative agency and through courts after administrative agencies have decided, though recent shifts in both Europe (Cassese, 2005) and the developing world (Thiruvengadam and Joshi, 2012; Uruena, 2012) are narrowing this difference.

After World War II, regulation in the United States became open to wider public participation. Administrative agencies must hold public hearings after announcing the topic of a rule they are considering. They must then justify the rule they issue according to the evidence they have. Often an organization concerned with the rule will bring the regulatory agency to court. Federal courts usually review the processes by which the rules were promulgated and decide whether the rule or decision is justified according to the evidence. What lawyers have won in the United States has been observed sometimes with horror, sometimes with envy in other nations.

Other nations do not rely so extensively on the equivalent of generalist courts to assess the procedures by which rules are enacted. The French have a specialized court that hears challenges to administrative decision making, the *Conseil d'Etat*, or Council of State. The *Conseil d'Etat* is staffed with people who have built careers within administration; the purpose is to have a court that will take into account public purposes, or the interests of the state, in deciding cases brought by individual challengers. In Britain, practitioners in regulation were frustrated enough with how their general jurisdiction courts supervised administrative decisions that the state created a version of a specialized administrative court in the 1970s (Sterett, 1997). Particular judges specialize in hearing

complaints about administrators. The political justification for both courts is that specialization in administrative complaints will lead to sensitivity to public purpose and an awareness of what can go wrong in administration. Germany, also, relies on a specialized administrative court staffed by a trained civil service judiciary.

In most countries, there are specialized bodies between frontline administrators and either generalist courts or upper level specialized administrative courts. These specialized bodies usually include representatives of relevant sectors (e.g., employers and union representatives in labor tribunals) in their staff. Members of specialized bodies are not always legally trained. Their procedures are often less formal than those of generalist courts, and those before them do not always have legal representation. The informality and discretion allowed most tribunals that provides substantial opportunity for a slip between formal statement of government policy and its meaning in particular cases.

Interest groups are also an important source of challenges to the general rules under which administrators work. Such challenges are probably more numerous in the United States than in any other nation (Kagan, 2000). However, social welfare groups in Western Europe have in recent years organized to challenge rules across diverse policy areas, including immigration and environmental regulation (Keleman, 2011). The expansion of standards via European Union directives and European Court of Justice decisions has made it more possible to challenge domestic regulation, or refusals to regulate, in Europe. And in the developing world, interest groups have begun to challenge domestic regulation in health, essential services, education, and water by invoking social and economic human rights commitments (Gauri and Brinks, 2010).

Finally, international and transnational agreements and standards have become increasingly important avenues that shape domestic regulation. For example, international treaties sometimes affect regulation in the same sector (e.g., in ozone regulation (Braithwaite and Drahos, 2000; Canan and Reichman, 1993)) and sometimes in different policy areas (for example bilateral treaties on international investment standards shape domestic environmental regulation (Szablowski, 2007)). Moreover, interest groups are increasingly developing detailed regulatory regimes of transnational standards outside (or in parallel with) states, (e.g., in forestry, finance, and labor protection) (Cashore et al., 2004; O'Rourke, 2003; Shaffer, 2012).

What Does It Cost?

Line items in government budgets for regulatory agencies do not actually state what regulation costs. To comply with regulatory requirements, businesses incur the costs of improving safety or at least documenting that they are trying to comply. Regulation involves trade-offs between effectiveness and other considerations. For example, we might want nursing homes to provide good care for people, but that is hard to measure. To the extent that we try to enforce it, we might direct effort in an organization toward documenting practices that do not quite get at caring, such as providing meals on time (Braithwaite, 1993). A more substantive mandate to care might better capture what we want, but it would be unenforceable.

In addition, different substantive regulations are acceptable to businesses and broader publics in different countries. For example, commitments to nondiscrimination in the United States, which critics see as more extensive than those in most other countries, impose costs through requirements of documentation of fair procedures. Such provisions do not require any particular substantive outcome. Other countries, however, employ approaches that would be unacceptable in the United States. For example, Sweden tried to implement employment equality in a way that could keep administrative costs low while resulting in real change, by setting employment quotas for women in jobs in which they were underrepresented (Brown and Wilcher, 1987). Britain, on the other hand, has relied on loose and open-ended definitions of nondiscrimination implemented through tribunals whose members are not legally trained and whose primary jurisdiction is not nondiscrimination law. The result seems to be a relatively inexpensive system that has done little to challenge discriminatory practices in the workplace (Kenney, 1992).

Business representatives have argued that the processes of American regulation are more resource intensive than those in other Western states: compliance requires more documentation, inspectors more readily impose fines, businesses can expect more public interest group confrontation, hearings, and possibly court battles (Kagan, 2000). However, concerns about the cost of formal regulation are now pervasive, and bureaucrats in both developed and developing countries are now often required to carry out regulatory impact analysis (and sometimes gain the permission of specialized bodies that enforce net benefit standards) before regulatory laws can be approved (Hahn and Muething, 2003; Raedelli and DeFrancesco, 2007; Morgan, 2003).

Despite concerns about the expense of regulation, enterprises sometimes choose to pursue the goals of regulation beyond those governments require, whether because compliance offices sometimes employ people who take the goals of regulation to be their mission, or because large corporations concern themselves with their public image as good citizens (Edelman, 1990; Gunningham et al., 2003). Compliance is not always a matter of direct orders.

Explaining Regulatory Styles: Political Institutions and Political Culture

Different approaches to regulation tend to fall into two very different styles: contentious with an emphasis on public procedures and rules, as against consensual without formal rules. A particularly important set of explanations for such differences stresses the historical emergence of national governance. A historical institutional approach holds that political institutions have shaped the emergence of different regulatory regimes. Those political institutions are in turn the result of large-scale historical processes. Two facets of this history are especially important: how insulated are regulatory institutions from electoral pressures, and how fragmented are political institutions in general?

In much of Western Europe, a career civil service insulated from politics was created in the nineteenth century (Kelman, 1981). Administrative arms of government often started as the personal servants of the monarch; the political environment within which they worked did not include mass electorates. Governments could develop bureaucracies insulated from political pressure, setting in place systems difficult to disrupt, no matter what cultural preferences there might be for a broader or more accessible or more aggressive system of regulation.

The insulation from the electoral politics that so profoundly shapes the civil services includes the judiciary. In civil law systems, judging is a career to which people are trained. The highest level administrative court in France, the *Conseil d'Etat*, is staffed with top level civil servants. Their charge is quite clearly to attend to complaints against administrators with an eye to maintaining the effectiveness of a regulatory regime; it is not a system designed to allow confrontation over the fundamentals of public policy. Even within British-style common law systems, judges in the general legal system are selected from the elite of the bar, who are narrowly trained and disinclined to confront administrators. In developing countries, the relatively weak institutional capacities of the civil service possibly create more contentious involvement of the courts in regulatory regimes (Uruena, 2012), and the relative lack of civil service insulation from politics certainly shapes regulatory politics in the global South, moving it along a spectrum between rules and deals (Dubash and Morgan, 2013).

Fragmentation of political institutions also contributes to contentious regulatory styles. In the United States, for example, the legislatures – Congress and the states – are not wholly within the control of the executive. Those who wish to insist on visions of regulation different from that of the executive can gain leverage in the legislature to do so, not least through mobilizing popular mistrust of closed procedures. The American system of formal rulemaking procedures and some openness in administration resulted first from the American Bar Association's mistrust of regulation and then from the politically distinct mistrust emergent in the 1960s and 1970s. Both gained leverage through Congress and through the courts, which had more generous standards for allowing people to sue than did courts in other nations.

By contrast, parliamentary systems, in which the government controls the legislative agenda, provide the government substantial control over how a regulatory bureaucracy will be organized and the forms accountability will take. Should a government believe it is best to include only responsible seeming or moderate interest groups in their discussion of regulation, or to limit checks such as a right for interest groups to sue administrators, they will find little institutionalized opposition (Vogel, 1986). From the point of view of government ministers, both in charge of government departments and sitting in parliament, such a capability only makes regulation more difficult. Blocking such capabilities leads to more consensual styles of regulation, for example, in the United Kingdom (Vogel, 1986). As with insulation from electoral pressures, political fragmentation has also been important in developing countries: for example, in understanding affirmative action policy in India (Parikh, 1997).

Some accounts of different regulatory styles focus more on cultural predilections (such as individualism or faith in authority) than on the institutional sources of shared meanings. From this perspective, US culture is individualist and assertive, while cultures in other Western countries are more deferential, in part based on a monarchical past and strong social hierarchies (Vogel, 1986). However, there are many ways in which the cultural explanation is incomplete. Deference, for example, hardly characterizes the upheavals of the 1960s and 1970s, pervasive throughout Western industrialized states. Cultural preferences may manifest in different types of legal change: in the United States, formal participation in rulemaking was institutionalized while other nation-states created state institutions such as ombudsmen to listen to complaints about administration in particular cases (Seneviratne, 2002). Cultural preferences are rarely the same across different areas of public life: in Britain, for example, a country cited as having informal regulatory practices in comparison to the United States (Vogel, 1986), land use planning has been contentious, rule bound, and full of litigation. A cultural explanation arguing that the British are more deferential than Americans cannot account for that contentiousness. An alternative institutional and historical explanation is relatively simple. The legal profession long made most of its income in land. By the time bureaucratic land use regulation emerged, the government had to take into account the interests of an already organized legal profession accustomed to litigating land disputes.

Historical institutional explanations are also better able to account for the ways in which supranational institutions harmonize regulatory requirements cross nationally. For example, within the European Union, the European Court of Human Rights and the European Court of Justice make decisions concerning the rules that nation-states use in areas as diverse as admitting immigrants, protecting the environment, providing health services, limiting sex discrimination, and determining the right to a family life or the right to travel. A perspective that takes nation-states as monolithic entities would see the supranational courts as an imposition on national autonomy. Since, however, not everyone within a nation-state agrees – some political activists want stricter regulation of pollution, or more openness to the families of settled immigrants – the introduction of supranational institutions makes for more complex alliances. State officials themselves are often not united, so supranational decisions or networks can strengthen the hand of one administrative office over another: this is particularly common in relation to free trade and competition standards (Maher, 2002; Shaffer, 2012).

Constituting Regulation: Rules and Discretion

No matter which institutions regulate, how many specific rules are made or how much regulatory contention emerges, discretion is an unavoidable part of all regulatory regimes.

National legislatures and executives may state general rules for regulation: that sex discrimination in employment is illegal, that businesses must reduce air pollution. Regulation is a complex task in which goals are often in tension – for example, to clean the air while ensuring that businesses that pollute do not have to close, or without severely curtailing

driving. Multiple and conflicting goals for complex organizations mean that what counts as compliance requires interpretation. Even in the United States, where the courts are in the business of continually clarifying the rules, the facts of a situation can be complicated enough that compliance with a rule is something that will entail negotiation between the regulator and regulated, which a court then only ratifies.

There are multiple levels in any regulatory setting where the exercise of discretion shapes the outcomes. Changing the ordinary practices of an organization is difficult. Where there are applicable rules or direct court orders against an organization, the organization must construe what it means to comply. Organizations have every reason to interpret decisions so that they fit with organizational priorities. For example, a court order to pay women equally with men in comparable jobs still leaves open what count as equivalent jobs, how equal the pay must be, and over how long a period it must be equalized, all of which will be up to an employer to determine (McCann, 1994).

The professional training of decision makers thus shapes what regulations mean. In employment discrimination law in the United States, personnel administrators interpret the law so as to require what they see as good management practices, which requires that people who work together get along. They do not often interpret the law as a matter of legal right, that is, as an enforceable claim that someone can make against his or her employer. Rather, personnel administrators are more likely to interpret problems as matters of personality conflicts (Edelman, 1993). Thus the presence of enforceable rights does not necessarily make regulation very different from, for example, enforcement of water pollution laws in Britain, where there are no clear rules and enforcement officials negotiate and bluff (Hawkins, 1984; Grabosky and Braithwaite, 1986). Even where tribunals or courts play an important role in overseeing the exercise of discretion, case-level administrators often interpret their instructions in light of what regulated businesses ordinarily do, and tribunals that oversee this often support it.

In recognition of the pervasiveness of discretion, scholarship increasingly focuses on both business organizations and administrative officials working in complex environments in which they mutually shape meanings of the law (Edelman, 1993; Harris and Milkis, 1996). Widespread shifts to 'process-oriented regulation' recognize this, and the effect is to place increased prominence on the uncertainty of human relationships within a regulatory environment, especially on the role of trust (Gilad, 2011). The more explicit recognition of the pervasiveness of discretion in regulatory design may also stem from the greater formal involvement of nonstate interest groups, and (perhaps relatedly), the increasing presence of transnational regulatory institutions that was noted above. This context is shaping regulation so as to require analysts to attend to reasons for convergence as much as differences between nation-states. The global context of regulatory implementation might lead to a two-level global economy – relative convergence among Western states (Braithwaite and Drahos, 2000), while developing countries produce goods in conditions much worse for workers. In response to the latter, the growth of certification as a nonstate regulatory regime has been a popular middle road in political terms, aiming to contain discretion that 'leaks' beyond traditional national regulatory regimes (Bartley, 2011). As a mechanism of social regulation, certification has a dual appeal both to companies who prefer private self-regulation and to social movements seeking to build new political institutions at the transnational level. Strong changes in on-the-ground practices as a result of such regimes, however, remain difficult to prove.

Abstract

Regulation takes many forms in practice, including price, quality, disclosure, privacy, and externality regulation. Popular methods for regulating the prices charged by public utilities include rate of return regulation, price cap regulation, and yardstick regulation. The optimal design of regulatory policy varies with industry structure and institutions, with regulatory objectives and policy instruments, and with the prevailing information structure.

Regulation is defined as "the act of controlling or directing by a rule, principle, [or] method" (Webster, 1989). This definition encompasses many forms of control by a variety of actors. The ensuing discussion will focus on the important form of economic regulation in which the government controls the activities of producers in order to enhance the well-being of the customers they serve. Particular emphasis will be placed on price regulation of utilities, i.e., suppliers of key services such as communications, electricity, and water.

Regulating with Accurate Information

When the average cost each firm incurs in serving customers (i.e., the firm's cost per customer) declines as the firm serves more customers, industry costs will be minimized when only one producer serves all customers. For example, the cost of providing local telephone service to a community is often lower when a single telecommunications network is constructed and operated than when multiple networks are operated. Similarly, the local distribution of electricity, water, and gas is often provided at minimum cost by a single firm. But if a single profit-maximizing firm faces no competition, consumers will have no alternative source of supply, and so an unregulated sole producer may have considerable freedom to charge high prices for its services. Regulation of the prices charged by a single (monopoly) supplier can help to protect consumers while permitting an industry configuration that minimizes the costs of serving customers.

Regulators typically consider many factors when setting prices. To illustrate, the US Postal Rate Commission is required to design a simple, transparent, just, and reasonable pricing structure for postal services in which the price charged for each service reflects the value of the service and generates revenue in excess of the corresponding production cost. In doing so, the Commission must consider many factors, including "the educational, cultural, scientific, and informational value to the recipient of mail matter" (Postal Accountability and Enhancement Act, 2006: Section 3622(b)).

To assess the basic principles that underlie the design of prices for regulated utilities more generally, consider first the case of an omniscient regulator who knows both how highly consumers value the essential services produced by the regulated firm and the minimum possible costs the firm incurs in serving customers.

Linear Pricing with a Single Output

Initially, suppose the regulated utility produces only one product. Also suppose the regulator desires to set the price for this product so as to maximize the aggregate welfare of all consumers while delivering sufficient profit to the firm to guarantee it will voluntarily serve customers at the established price. Consumer welfare measures the value consumers derive from their purchase and consumption of the product. A firm's profit is the difference between the revenues it receives and the costs it incurs. Profit is a measure of producer welfare. To maximize consumer welfare while delivering at least the minimum required level of producer welfare, the regulator must set the price consumers pay for each unit of the product they purchase so as to deliver the largest possible sum of consumer and producer welfare. This welfare-maximizing price is equal to the extra (or marginal) cost the firm incurs in producing the last unit of the product it sells. This is because consumers will continue to buy more of the product as long as the extra value they receive from doing so exceeds the price they must pay for an additional unit of the product. Therefore, when the price reflects the producer's marginal cost of production, consumers will purchase additional units of the product whenever the value they derive from consumption exceeds the cost of allowing that consumption. Consequently, a regulated price that reflects the producer's marginal cost of production will ensure the level of output that maximizes the combined welfare of consumers and the firm.

However, when unit production costs decline as the firm produces more output, a price set equal to the marginal cost of producing the last unit of output will cause the firm to suffer a financial loss. For all but the last unit produced, the compensation the firm receives (i.e., the price) will be less than the incremental production cost it incurs. To ensure that the total revenue the firm receives does not fall below the total production cost it incurs, the regulator must raise the authorized price above the level of marginal cost. A price equal to the firm's average cost of production at the prevailing level of production will deliver the highest possible level of welfare to consumers while ensuring that the regulated firm's costs do not exceed its revenues.

Nonlinear Pricing

A regulator might contemplate implementing a pricing structure in which customers do not simply pay the same price for

 http://dx.doi.org/10.1016/B978-0-08-097086-8.71034-8

each unit of the product they purchase. For example, each customer might be charged both a fixed participation fee that does not vary with the amount of the product purchased and a constant unit price for each unit purchased. Under such a pricing structure, the unit price might be set equal to the regulated supplier's marginal cost of producing the last unit of output it sells and the participation fee might be set to recover exactly the deficit the firm incurs (i.e., the difference between the total revenue it receives from sales and the total production costs it incurs) when it sells its product at the specified unit price. This pricing structure would deliver the maximum possible level of consumer welfare while ensuring nonnegative profit for the firm, provided the participation fee is not so onerous as to compel some customers to terminate all purchases of the regulated product (Wilson, 1993). In practice, large participation fees are often viewed as unduly onerous for consumers with limited resources. Consequently, particular concern for the well-being of these consumers or general concerns with equity and fairness can limit the use of participation fees and other alternatives to constant unit prices.

Linear Pricing with Multiple Outputs

Now consider the more common setting in which the regulated utility produces multiple products (for example, both rural and urban telephone service). Also suppose the regulator chooses to implement only a constant unit price for each regulated product. Since the prices charged for different products can vary, there are many different ways in which the regulator can raise prices above marginal production costs while ensuring that revenues match total operating costs exactly. To maximize the combined welfare of all consumers, the regulator will increase the price of a regulated product further above its marginal cost of production the less sensitive consumer demand is to the price of the product. In particular, the regulator will set the price of a product close to its marginal cost of production when a higher price would cause consumers to severely curtail their purchases of the product. In contrast, the regulator will raise the price of a product well above its marginal cost of production when doing so does not cause consumers to reduce their purchases of the product significantly. This pricing policy secures the greatest combined welfare for consumers by limiting the aggregate reduction in consumption that arises as prices are raised sufficiently far above marginal production costs to generate revenues that match production costs (Baumol and Bradford, 1970).

Quality Deterioration and Cream Skimming

As noted above, regulators do not always seek solely to maximize the aggregate welfare of consumers. Consequently, in practice, regulated prices are not always raised above marginal costs by greater amounts the less sensitive consumer demand is to the price. In fact, some prices (e.g., those for rural, residential telephone service) may be set below marginal production costs, while other prices (e.g., those for telephone service to urban business customers) may be set well above marginal production costs. Such prices may arise from fairness and equity concerns, for example. Pricing patterns of this sort can introduce two important problems: quality deterioration and cream skimming.

When the price of a product is set below its marginal cost of production, each extra unit of the product the firm sells reduces its profit. Consequently, the firm would secure greater profit if consumers purchased fewer units of the product. One way to induce consumers to purchase fewer units of a product is to reduce the quality of the product. Therefore, when prices are set below marginal production costs, the regulator may need to impose penalties on the firm if the level of service quality it delivers is found to be inadequate.

When prices are set above the cost for some products and below the cost for other products, competitors may find it profitable to supply only those products for which price exceeds the cost and leave the incumbent regulated firm to supply those services for which price is set below the cost. For example, unless they are prohibited from doing so, competitors may provide telecommunications service only to large businesses in urban areas. This practice is known as cream skimming. A regulator can prevent cream skimming by barring potential competitors of the incumbent regulated firm from providing services in the regulated industry. Such entry prohibitions, though, can hinder industry performance by precluding the operation of firms that have lower operating costs than the incumbent supplier and by removing the discipline that the threat of entry can impose on the incumbent firm. Furthermore, competitors are sometimes able to circumvent prohibitions on entry by developing and marketing substitute products. A regulator can limit incentives for cream skimming by setting prices that more closely reflect the incumbent firm's operating costs. When prices reflect costs in this manner, entry will typically be encouraged only when a competitor can satisfy consumers' needs at lower cost than the incumbent supplier can.

Regulation in Two-Sided Markets

Suppliers of network services sometimes serve two distinct groups of constituents. For example, Internet service providers (ISPs) serve both retail consumers and content providers (CPs). An ISP allows retail customers to access the content provided by CPs and simultaneously provides CPs with access to retail consumers. In principle, an ISP could charge both 'sides' of the market, i.e., charge retail customers for Internet access and charge individual CPs for making their content available to the ISP's retail customers. The welfare-maximizing price charged to one side of the market depends on the marginal cost of serving that side of the market and on the extent to which a price above marginal cost reduces Internet use by both retail customers and CPs (Rochet and Tirole, 2006). In practice, an ISP charges its retail customers for Internet access but typically does not charge individual CPs for allowing the ISP's retail customers to access CP content. This asymmetric pricing policy – commonly referred to as net neutrality – often is encouraged on the grounds that it promotes the widespread dissemination of ideas, facilitates the free exchange of information and opinions, and encourages innovation by CPs. However, ISPs contend that an inability to charge CPs limits the ability of ISPs to manage network congestion, reduces the scale and scope of beneficial network investment an ISP can afford to undertake, and

inhibits the ISP's ability to tailor network capabilities to the idiosyncratic needs of diverse CPs (Schuett, 2010).

Regulating with Limited Information: Incentive Regulation

When, as presumed above, the regulator is well informed about the firm's operating capabilities, the regulator can set prices to generate revenues that exactly match production costs when the firm operates efficiently (i.e., when it incurs only the minimum possible cost required to serve customers). When the regulator is not perfectly informed about the firm's capabilities, the regulator cannot simply require the firm to operate efficiently. Instead, the regulator must motivate the firm to reduce its operating costs toward their minimum possible levels. There are a variety of techniques the regulator can employ to do so. These techniques constitute elements of what is termed incentive regulation.

Regulatory Lag

When prices are set to match realized production costs only periodically (e.g., once every 3 or 4 years) rather than continually, the firm derives some financial benefit from reducing its operating costs. The longer the period of time before prices are reduced to match lower realized operating costs, the more pronounced is the firm's incentive to reduce its costs. On the other hand, the longer prices are permitted to remain above operating costs, the longer consumer welfare is held below the level that could be secured given the firm's realized costs. This trade-off determines the optimal length of time between price revisions, i.e., the optimal regulatory lag.

Price Cap Regulation

Price cap regulation has become commonplace in many regulated industries. Price cap regulation incorporates a form of regulatory lag while delegating some pricing discretion to the regulated firm. The typical price cap regulation plan specifies a price cap period (often 4 or 5 years) and a maximum rate at which the regulated firm's inflation-adjusted prices can rise annually, on average, during this period (Sappington and Weisman, 2010). The firm's realized costs and earnings are usually reviewed at the end of the specified price cap period, and often employed to update estimates of the pricing restriction that would allow the regulated firm to secure a reasonable level of earnings in the next price cap period. When the firm's realized performance is employed to set future standards, the firm's incentives for exceptional performance are dulled. However, price cap regulation provides some incentives for cost reduction by instituting an explicit regulatory lag.

By controlling the rate at which regulated prices can increase on average, price cap regulation affords the firm some discretion in setting prices for individual services. This discretion can help the regulated firm to limit undesirable cream skimming by realigning prices to more closely match production costs. However, this discretion can also enable the firm to raise certain prices that the regulator prefers to remain low (e.g., the price of local telephone service to rural residential customers). To limit the firm's ability to implement undesired pricing structures, price cap regulation plans often prohibit the firm from raising significantly the prices of certain specified products.

Earnings Sharing Regulation

By providing incentives to reduce operating costs, price cap regulation can simultaneously provide incentives to reduce service quality, since superior quality is often more costly to provide. By allowing prices to diverge from realized costs for considerable periods of time, price cap regulation also can admit earnings that depart significantly from expected levels. To mitigate these potential problems, an earnings sharing plan is sometimes appended to price cap regulation. An earnings sharing plan requires the firm to share with its customers a fraction of realized earnings above (and often below) specified thresholds. Such sharing helps to insure the firm and the regulator against extremely high (and low) earnings, but at the expense of reduced incentives for exceptional performance (Lyon, 1996).

Yardstick Regulation

In certain settings, yardstick regulation can be employed to provide strong incentives for superior performance while limiting the risk of extreme earnings. Under yardstick regulation, the standards to which one firm is held are based upon the performance levels achieved by other firms. To illustrate, in the British water industry, the prices and service quality standards that are imposed on the monopoly provider in one jurisdiction are linked to the costs and service quality levels achieved by monopoly producers in other geographic regions (Abbott and Cohen, 2009).

When firms face similar operating circumstances, yardstick regulation can enable the regulator to impose a reasonable but challenging performance standard on the regulated firm without basing this standard on the firm's own historic performance. Consequently, yardstick regulation can ensure reasonable earnings for the regulated firm while providing the firm with strong incentives for superior performance. However, these desirable outcomes can only be secured via yardstick regulation if the firms are known to face similar operating circumstances or if all relevant differences in their operating circumstances are well understood. In the absence of this knowledge, the standards imposed under yardstick regulation can result in extreme earnings, much like under price cap regulation. Yardstick regulation may also encourage collusion among the firms that are implicitly being compared. By agreeing to reduce their performance below achievable levels, the firms can effectively relax the constraints imposed by yardstick regulation (Tangeras, 2002).

Franchise Bidding

Even when there is a single regulatory jurisdiction and a single producer in the industry, a regulator may still be able to harness the discipline of competition by structuring competition for the industry. The regulator may allow potential producers to bid for the right to serve as the sole producer in the industry. When

the potential producers have similar abilities and similar information about operating circumstances, intense bidding competition for the market can secure for consumers the low prices and high service quality that competition among producers in the market might otherwise provide. However, successful franchise bidding requires that all relevant performance requirements be specified completely in advance, and that the regulator and firm both adhere precisely to the terms of the franchise contract once a producer has been selected. If the regulated firm can renege on its responsibilities after it is installed as the sole producer, or if the regulator can demand more services from the selected producer than it originally agreed to provide, franchise bidding can fail to deliver the maximum possible attainable level of consumer welfare (Klemperer, 2002).

Regulatory Options

When the regulated firm has better information than the regulator about its operating capabilities, consumers are often best served when the regulator allows the firm a choice among regulatory plans. A careful structuring of the options afforded the firm can induce it to employ its superior information to choose a plan that best serves consumers (Laffont and Tirole, 1993; Armstrong and Sappington, 2007).

To illustrate this point, suppose a regulator decides to impose price cap regulation on a firm rather than allow the firm to choose between price cap regulation and cost-plus regulation, whereby prices are reset frequently to match realized production costs. To limit the likelihood of financial distress, the regulator may not insist that prices decline rapidly. In contrast, when the firm has the option to choose cost-plus regulation, the regulator can impose more stringent limits on price increases under price cap regulation without the fear of causing financial distress. If the firm believes it will be unable to realize adequate earnings under the proposed price cap regime, it will choose to operate under cost-plus regulation instead. But if the regulator has not overestimated the firm's capabilities in setting the challenging requirements of the price cap regime, the firm will choose this regime and deliver its pronounced benefits to consumers.

Regulation in Vertically Related Industries

Regulated firms sometimes supply both inputs and final products. Inputs are products that firms employ to make other products. Final products are those that customers consume, and that are not used to make other products. For example, an incumbent supplier of telecommunications services may both deliver key inputs (e.g., network access and message transport) to rival suppliers and sell telephone service to retail customers. Additional considerations arise in such settings.

Limiting the Disadvantaging of Retail Rivals

A vertically integrated supplier (VIS) may exploit its position as the supplier of key inputs to rivals to hinder their operations. For example, consider a setting where the VIS is a relatively efficient supplier of the retail product, and so would secure the highest level of profit if it were the sole supplier of the retail product. In such settings, the VIS will be inclined to charge a very high price for the inputs it supplies to retail rivals (and/or severely limit the quality of the inputs) in order to induce the rivals to terminate their market activities. Regulation of input prices and/or input qualities that limits such exclusionary behavior can promote competition among retail suppliers in such settings and thereby benefit retail customers.

Although a VIS often will have an incentive to disadvantage retail rivals, this is not always the case for at least two reasons. First, if a VIS derives substantial profit from selling its inputs to retail rivals, activities that limit the sales of retail rivals can reduce their purchases of inputs from the VIS and thereby diminish the profit of the VIS (Sibley and Weisman, 1998). Consequently, regulated input prices above marginal production costs can limit the incentive of a VIS to hinder the operations of retail rivals (Beard et al., 2001). Second, activities that reduce the demand for rivals' retail products can induce the rivals to lower the prices they charge for their products. Such price reductions reduce the retail profit of the VIS, and so the VIS may refrain from activities that reduce the demand for rivals' retail products (Mandy and Sappington, 2007).

Regulating Input Prices

In addition to limiting the incentive of a VIS to hinder the operations of retail rivals, an input price above its marginal cost of production can help to limit cream skimming and ensure that downstream production is carried out by the least-cost suppliers. To illustrate this point, suppose that if the input supplier operates downstream, the prices it charges there are regulated. Further suppose that the price of one downstream product (called product A) is set at a level (p^A) that exceeds the supplier's marginal cost of production (perhaps to facilitate a price below marginal cost for another product). If the price of the essential input is set equal to its marginal cost of production in this setting, a downstream producer may be able to serve all consumer demand for product A profitably, even though its marginal cost of production ($\tilde{c}^A$) exceeds the corresponding cost (c^A) of the input supplier. The higher cost producer can set a price below the regulated price for product A and still secure positive profit if its cost disadvantage ($\tilde{c}^A - c^A$) is smaller than the regulated profit margin on product A ($p^A - c^A$). To preclude operation by higher cost competitors, the price of the essential input can be raised above its marginal cost of production by the amount of profit ($p^A - c^A$) the input supplier foregoes when it provides the input to competitors (Armstrong, 2002).

Regulating Market Structure

The vertical divestiture of a VIS can reduce its incentive to disadvantage retail operators. When the supplier of a key input has no direct financial interest in any retail supplier, the input supplier may find it most profitable to enhance, rather than hinder, the capabilities of all retail suppliers. In many settings, though, the complete separation of the wholesale and retail operations of a formerly integrated firm can increase the firm's production costs, complicate its planning activities, and disrupt industry operations. Therefore, regulators in some industries

(e.g., the telecommunications industry) often view the vertical divestiture of an industry supplier as a last resort (Ofcom, 2005).

Vertical divestiture has been promoted in the electricity industry to help ensure that transmission companies do not provide network access on differentially favorable terms and conditions to affiliated generators. Such discrimination has the potential to raise the prices customers pay for electricity and to discourage investment in generation capacity by independent electricity generators (Hogan, 2002; Joskow, 2005).

Additional Roles of Regulation

Although regulation often focuses on the prices that utilities charge for their services, regulation can assume other forms.

Service Quality Regulation

As noted above, input quality regulation can help to limit the ability of a VIS to disadvantage retail rivals by supplying them with low-quality inputs. Regulation of the quality of retail services also can benefit consumers. For example, when consumers lack the expertise required to evaluate the benefits associated with different levels of service quality (e.g., product safety features), the imposition of service quality standards can help to ensure producers deliver the quality levels that best serve consumers' needs (Viscusi, 2007).

Disclosure Regulation

In settings where consumers understand the benefits of different levels of service quality but have difficulty observing the quality of a product before it is purchased, consumers can benefit from regulation that mandates information disclosure. Disclosure regulation can require producers to inform consumers about key elements of product quality (e.g., the risks associated with certain financial or pharmaceutical products) and thereby help consumers choose the products and services that best serve their needs.

Privacy Regulation

Although consumers can benefit from the mandated disclosure of certain types of information, they may object to the disclosure of other types of information. Consumers reveal information about their preferences and may provide additional personal information (e.g., age, gender, marital status, and residence location) when they engage in commercial transactions (e.g., purchasing a product or applying for credit). Conceivably, advertisers might purchase personal customer information from merchants in order to be better able to tailor advertising activities to the tastes and interests of individual customers. Although such tailoring might both increase the profits of sellers and reduce the amount of irrelevant advertisements consumers receive, some consumers may object to the lack of privacy implied by the sharing of their personal information. Regulation to limit such sharing that is not explicitly authorized by consumers therefore has the potential to enhance consumer welfare in some settings (Evans, 2009).

Regulation of Externalities

In certain instances, production activities can impose negative externalities on society. A negative externality generated by a production activity is a cost the activity imposes on individuals not directly involved in the activity. For example, some production processes may expel harmful pollutants into the surrounding land, water, or air. If no restrictions are placed on producers' rights to expel pollutants into the environment, producers may produce more than the surplus-maximizing level of pollution. This is the level of pollution at which the social damage that would be caused by an additional unit of pollution is exactly equal to the social cost that must be incurred to eliminate that additional unit of pollution. Pollution in excess of the surplus-maximizing level imposes social damage that exceeds the cost of eliminating the extra pollution. In contrast, the cost of reducing pollution below the surplus-maximizing level exceeds the social benefits derived from the reduction in pollution.

Various regulatory policies can be employed to control environmental pollution and other types of negative externalities. For instance, direct taxes (effluent fees) can be imposed on pollution when it is readily observed and measured. By setting the tax on pollution equal to the marginal social damage caused by the pollution, the producer can be induced to realize the surplus-maximizing level of pollution. When the level of pollution produced by a firm is difficult to measure, taxes can be imposed instead on the products whose production causes pollution, or on inputs (such as gasoline) to the activity (automobile driving) that causes pollution. The use of specific pollution abatement technologies can also be mandated.

Some governments have introduced tradable pollution permits to limit pollution. Each permit entitles its bearer to emit one unit of pollution (e.g., 1 ton of sulfur dioxide). Polluting firms are able to buy and sell permits at prices determined by the available supply of and demand for these permits. A key potential benefit of tradable permits is that they promote pollution abatement at minimum cost. Producers that are able to reduce the pollutants they expel at a cost below the prevailing price of a permit will find it profitable to do so and sell any permits they own. In contrast, producers for whom pollution abatement is more costly than the price of a permit will continue to expel pollutants but will pay for the right to do so (Burtraw et al., 2005).

Sector Regulation

While this discussion has focused on price regulation of utilities, other forms of regulation prevail in other industries. To illustrate, regulations designed to avoid systematic industry failure are common in the financial sector. The *Dodd–Frank Wall Street Reform and Consumer Protection Act of 2010*, for instance, limits the ability of banks to invest consumer deposits insured by the US government in risky ventures. The Act also attempts to prevent financial institutions from becoming 'too big to fail', and restricts the use of public funds to rescue private institutions that do fail (Acharya et al., 2011).

In the health care industry, legislation like the *Patient Protection and Affordable Care Act of 2010* requires US citizens to purchase health insurance, provides corresponding

financial subsidies to low-income citizens, attempts to enhance competition among suppliers of health insurance, and limits the ability of these suppliers to discriminate against individuals with preexisting chronic health problems (Kaiser, 2013).

Competing for Regulatory Benefits

This discussion illustrates some of the ways in which the regulation of producer activities can be designed to benefit consumers. It is important to note, however, that regulation may not always serve this role in practice. Because regulators typically have the power to deliver benefits to some parties and impose costs on others, the affected parties will have an incentive to try to secure favorable treatment from regulators. When industry producers are better organized and have more at stake than industry consumers, regulation that benefits producers at the expense of consumers can arise (Bo, 2006). For example, new competitors may be barred from an industry even though their entry and operation would be in the best interest of consumers. These realistic possibilities merit careful consideration when evaluating the benefits and costs of existing and proposed regulations.
